Abstract

Objectives: To assess the prevalence of venous thromboembolism (VTE) risk in acutely ill surgical and medical patients in selected acute care centres in the Arabian Gulf States, and to determine the proportion of at-risk patients who received effective prophylaxis in accordance with 2004 American College of Chest Physicians (ACCP) guidelines. **Materials and Methods:** Eight hospitals from 3 countries (Kuwait, Kingdom of Saudi Arabia, and United Arab Emirates) contributed to the global ENDORSE (Epidemiological International Day for the Evaluation of Patients at Risk for Venous Thromboembolism in the Acute Hospital Care Setting) study. Medical records were reviewed for all the in-patients aged ≥ 40 years admitted to medical wards, and in patients aged ≥ 18 admitted to surgical wards. The VTE risk and recommended prophylaxis were assessed according to the 2004 ACCP guidelines. **Results:** Of 1,291 evaluable patients, 801 were considered at risk of VTE; 391 (48.8%) surgical patients and 410 (51.2%) medical patients. Of the 801 patients, 322 (40.2%) received ACCP-recommended VTE prophylaxis; 159 (40.7%) of

surgical patients and 163 (39.8%) of medical patients. **Conclusions:** The data showed that VTE prophylaxis was underutilized in high-risk hospitalized patients. We recommend that active measures should be implemented in acute care centres in these Arabian Gulf countries to ensure identification of patients at risk of VTE and institute the appropriate prophylaxis.

Introduction

Venous thromboembolism (VTE) prophylaxis in acute care medical centres has been proven to be effective in reducing the rate of VTE in high-risk patients [1, 2]. Several post-mortem studies have shown a significant hospital VTE-related mortality up to 10%, thereby making VTE one of the main causes of death in hospitalized patients [3–5]. Awareness of potential risk factors that put hospitalized patients at risk of VTE and implementation of evidence-based thromboprophylactic measures in these patients have been published in several guidelines [6–10]. Despite the publication of these guidelines, some of them updated annually, a large number of practicing physicians and surgeons still underestimate VTE risk and

thus implement inadequate VTE prophylaxis practices [11–13].

The ENDORSE (Epidemiologic International Day for the Evaluation of Patients at Risk of Venous Thrombosis in the Acute Hospital Care Setting) study was the first published global multicentre cross-sectional study that explored the percentage of acute care hospitalized patients at risk of VTE at any given time. It also looked into adherence to strict VTE prophylaxis practices according to risk stratification in surgical and medical patients as published in the American College of Chest Physicians (ACCP) guidelines [14].

The need to explore VTE risk estimation and adequacy of VTE prophylactic strategies in Arabian Gulf countries is of great importance since data in this area are rare. There is only one such study [15], which explored VTE risk factors, its rate in surgical and medical wards and the appropriateness of using pharmacologic anticoagulation. This study showed a significant VTE rate in both surgical and medical patients. In addition, there was inappropriate utilization of pharmacologic anticoagulants in patients with established VTE [15].

The objectives of this study were to use the global ENDORSE study to determine the prevalence of patients at VTE risk in selected acute care hospital settings in the Arabian Gulf region; to find the proportion of patients at VTE risk that received thromboprophylaxis in accordance with ACCP 2004 guidelines [7].

Materials and Methods

The methodology of the study has been described in the global ENDORSE publication [14]. Briefly, hospital selection was done randomly from authoritative lists of acute care centres in 3 Arabian Gulf countries: Kuwait, Kingdom of Saudi Arabia (KSA) and United Arab Emirates (UAE). Hospitals with more than 50 beds that admit patients with acute and chronic medical disorders as well as scheduling routine surgical procedures were considered eligible for inclusion in the study. Approval of the local hospital authorities was obtained before collecting the data. Signed patient consent was not required.

Patients' data, including demographics, diagnosis on admission, VTE risk factors, factors associated with risk of bleeding, duration of hospital stay and VTE prophylaxis used including the dosage (in accordance with ACCP guidelines), were extracted from the patients' medical records. Standardized case report forms were used by trained medical personnel to extract the data.

The survey included patients who were hospitalized in an eligible ward at the time of data collection. One day was considered adequate for each eligible ward to complete the data collection forms. The eligibility criteria included those patients who are ≥ 40 years of age in eligible medical wards and patients aged ≥ 18 in eligible surgical wards based on ENDORSE recommendation

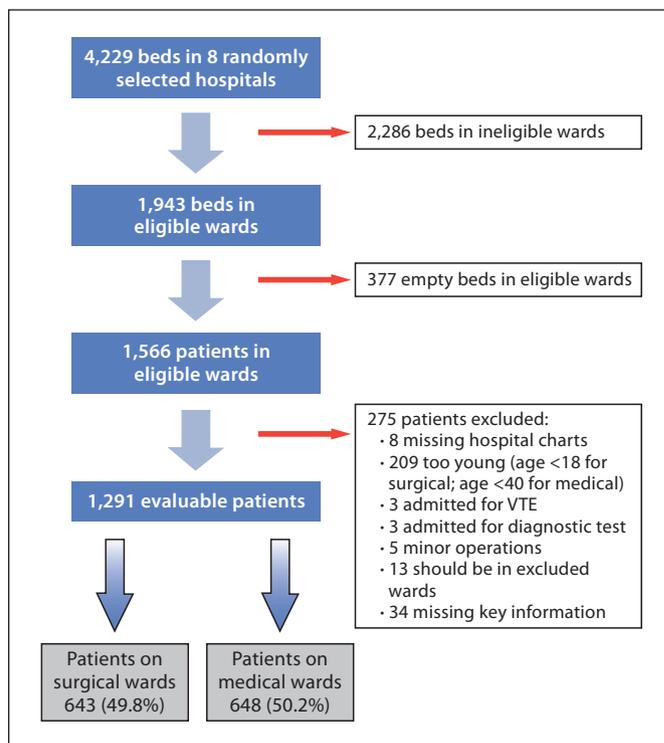

Fig. 1. Selection of the study population.

[14]. In addition, patients assessed for VTE risk included acutely ill medical patients, patients hospitalized for major trauma or undergoing a major surgical procedure requiring general or epidural anaesthesia for at least 45 min. VTE risk assessment in surgical patients was classified as being at highest, high, moderate or low risk for VTE. Data on VTE thromboprophylaxis that had been collected were only those that followed ACCP 2004 guidelines. However, thromboprophylaxis duration could not be assessed due to the cross-sectional nature of the study.

Patients were considered ineligible for VTE thromboprophylaxis if they presented or were at risk of the following: intracranial haemorrhage, liver impairment, bleeding at hospital admission, an active peptic ulcer, and known bleeding disorder. The selection algorithm of eligible patients and the number of the evaluable patients in surgical and medical wards are shown in figure 1.

Statistical analyses of the global ENDORSE report were used in this study [14].

Results

Of the 1,291 evaluable patients in the 3 countries, 801 (62%) were considered to be at risk of VTE. Patient characteristics and indications of admission in surgical and medical wards are listed in table 1.

Table 1. Characteristics and reasons for hospitalization of eligible patients

Several VTE risk factors were identified that were present prior to hospital admission, and those acquired during hospitalization. Immobility, cardiac failure and chronic lung disease were the most common risk factors prior to admission, whereas immobilization, intensive care unit/coronary care unit admission and mechanical ventilation were among the common acquired factors during hospitalization (table 2).

The most common contraindication for pharmacological prophylaxis in surgical patients was non-steroidal anti-inflammatory drugs, while in medical patients, it was the use of aspirin and renal impairment. There were also differences in the use of aspirin and non-steroidal anti-inflammatory drugs among the countries. In Kuwait, aspirin was more commonly used in all admitted patients as compared to the KSA and UAE, whereas non-

ICU = Intensive care unit; CCU = coronary care unit.

steroidal anti-inflammatory drugs were more commonly used in the KSA as compared to Kuwait and the UAE (table 3).

Pharmacological prophylaxis was the most frequently used method of prophylaxis in surgical and medical patients. Mechanical prophylaxis was a less commonly used method. Graduated compression stockings were the preferred method of mechanical prophylaxis especially in surgical wards (table 4).

Of the 801 patients at risk of VTE, only 322 (40.2%) received ACCP-recommended prophylaxis. The overall use of VTE prophylaxis in high-risk patients in each country and in surgical and medical departments is given in table 5.

Discussion

Because only 40.2% of high-risk patients received ACCP-recommended VTE prophylaxis, VTE prophylaxis was underutilized in the participating centres in the Arabian Gulf region. This finding is lower than approximately 50% reported in the worldwide utilization of VTE prophylaxis in the ENDORSE study [14]. In addition,

there was no significant difference between surgical and medical patients in utilizing VTE prophylaxis because 39.8% surgical patients and 40.7% medical patients at high risk received ACCP-recommended prophylaxis in contrast to the global ENDORSE findings reporting that more surgical than medical patients received VTE prophylaxis [14].

When we examine the data more closely by country, the utilization of VTE prophylaxis in the KSA in high-risk medical patients was 62%, higher than in Kuwait (33.5%) and the UAE (33.1%). In fact, it is higher than the average global result in medical patients, which was reported as 40% [14]. On the other hand, more surgical patients at risk of VTE received ACCP-recommended prophylaxis in Kuwait (58.1%) as compared to the KSA (32.30%) and UAE (43.2%). These results seem to indicate that a large proportion of practicing physicians and surgeons in the Arabian Gulf area lack the awareness and knowledge of already published evidence-based guidelines on everyday practice of VTE prophylaxis. It may also indicate the existence of a significant number of patients with contraindications to pharmacologic prophylaxis in this series that lead to hesitancy of health care providers in initiating pharmacologic prophylaxis (ta-

GCS	25 (9.2)	11 (3.9)	9 (3.7)	32 (8.2)	13 (3.2)	45 (5.6)

The IPC, foot pump and GCS were used separately in patients who had contraindications to anticoagulant based on the treating physician's decision. LMWH = Low-molecular-weight heparin; UH = unfractionated heparin; VKA = vitamin K antagonists; IPC = intermittent pneumatic compression; GCS = graduated compression stocking.

Table 5. Proportion of high-risk patients who received VTE prophylaxis according to ACCP guidelines by country and department

	Kuwait, n (%)	KSA, n (%)	UAE, n (%)	Total, n (%)
Prophylaxis according to ACCP	109 (40.2)	119 (41.9)	94 (38.2)	322 (40.2)
Surgical	43 (58.1)	62 (32.3)	54 (43.2)	159 (40.7)
Medical	66 (33.5)	57 (62.0)	40 (33.1)	163 (39.8)

ble 3). Equally important, there was also a lack of unified VTE risk assessment guidelines in the medical centres in the 3 participating Arabian Gulf countries. Thus, regional efforts should be carefully planned to raise awareness among health care professionals through implementation of educational programmes and adoption of mandatory VTE risk stratification charts in the wards.

Unfractionated heparin and low-molecular-weight heparin were the commonest forms of pharmacologic prophylaxis that were used in the Arabian Gulf States (table 4). There was a preference towards unfractionated heparin over low-molecular-weight heparin in KSA hospitals. In addition, unfractionated heparin was the commonly used pharmacologic prophylaxis in the UAE. The preferable use of unfractionated heparin has many possible explanations that include drug availability because of its cheap price, longer experience, and availability of a specific antidote to unfractionated heparin. Graduated compression stocking was used more often than intermittent pneumatic compression because of the limited availability of intermittent pneumatic compression machines on the wards. In addition, foot pumps were never reported to be utilized in the region. The effectiveness of mechanical VTE prophylaxis alone or in combination with pharmacologic prophylaxis has been shown in many studies to be the recommended method in high-risk patients as published in guidelines [12, 16–18]. Mechanical prophylaxis was rarely used in high-risk patients in this study. This underutilization of mechanical prophylaxis supports the notion that more is needed toward raising

the awareness of using different forms of VTE prophylaxis when a contraindication to anticoagulants is indicated [17–19].

There are several limitations to this ENDORSE study. Only 8 centres participated in the study and this may not be representative of thromboprophylaxis practices in the other medical centres. The data were obtained from the medical records rather than from direct interview with the patients. Since the ENDORSE study was a cross-sectional study, hence, long-term follow-up on adherence of health care providers to published VTE prophylaxis guidelines was not assessed.

Conclusion

The findings of the ENDORSE study in the 3 Arabian Gulf States showed that VTE prophylaxis was underutilized in surgical and medical patients at risk of VTE. We therefore recommend that regional efforts should be initiated to raise awareness of VTE risk and ensure that at-risk patients receive appropriate prophylaxis through mandatory hospital-based strategies, and implementation of evidence-based guidelines.
