Children with Autism Spectrum Disorder (ASD) engage in less physical activity (PA) and exercise, and on intervention procedures for children with ASD at all three levels, or “perspectives:”

1. Individual
2. Family
3. Community

The purpose of this poster is to:

- Describe Chinese-American cultural variables that may influence participation in PA and related health challenges in children with ASD.
- Community-engaged approaches for addressing PA and related health challenges in children with ASD.

Multi-level Determinants of PA for Children with ASD

### Perspective Barriers Findings

**Individuals**

- Learning:
  - Physical activity (PA) skills were difficult to learn.
- Communication:
  - Fewer adolescents with ASD believed that PA was a way to make friends, and they had problems in communicating with others.
- Beliefs:
  - Fewer adolescents believed that PA would be good for their health.
- Screen Time:
  - Screen time and PA – both in number of hours and type of PA were inversely correlated. But children with ASD showed better responses to verbal directives delivered through video.
- Motor skills:
  - Motor difficulties affected the ability to perform PA.
- Age:
  - The older the children, the less they were to be engaged in PA.
- Supervision:
  - More supervision was needed when the children engaged in PA.
- Skills to promote inclusion:
  - Parents lacked skills for helping their children to make friends.
- Fear of being injured:
  - Parents feared that their child might be hurt during PA, and that their children might hurt others.
- Peers:
  - Children with ASD had difficulty talking with typically developing peers, who in many cases did not want to play with them.
- Time:
  - Parents wanted their children to learn to work, which took more time to complete as compared with typically developing children. Accordingly, children with ASD had less time for PA.

Families

- Transportation:
  - Children with ASD had short-term challenges with transitions, which prevented them from moving indoors to outdoors and back, and from going to new places.
- Opportunities:
  - Opportunities for children with ASD to enrol in PA were lacking and too costly.
- Staff:
  - Lack of available programs and inexperienced personnel influenced the extent to which the needs of children with ASD were met.
- Equipment:
  - Too few or inappropriate pieces of equipment were available for children with ASD to perform PA.

Community

- Opportunities:
  - Opportunities for children with ASD to enrol in PA were lacking and too costly.
- Staff:
  - Lack of available programs and inexperienced personnel influenced the extent to which the needs of children with ASD were met.

Community-engaged Approaches for Addressing PA and Related Health Challenges in Children with ASD

Few studies have employed community-based participatory research (CBPR) approaches to address the general needs of children with ASD, and to our knowledge no published studies have focused on PA in these children. However, one study used a community-based approach with adults with developmental disabilities. Bazza, Zeldin, and Garro (2007) used a community-based approach to design a seven-month Healthy Lifestyle Change Program (HLCP) to address obesity and overweight in adults with developmental disabilities, aged 18-65. The authors conducted a pre-post test evaluation of HLCP, which was designed to increase knowledge, skills and self-efficacy about health, nutrition and fitness in participants. Measures were taken on BMI, abdominal girth, self-reported nutrition, and PA level to determine the effectiveness of the program. Data indicated that HLCP was associated with improved lifestyles, weight loss and increased community capacity, suggesting community-based approaches may be effective and efficient way to encourage participants to be engaged in the health and exercise programs.

Chinese-American Cultural Variables: Do they Influence Participation in PA in Children with ASD and their Families?

- Chinese culture is quite different from American culture. Immigrated Chinese-Americans have had to adapt to the American culture. Although some studies were identified that suggested Chinese-American cultural variables may influence participation in PA in typically developing children, no research was found on children with ASD.
- Acculturation can influence a person’s beliefs, attitudes, and behaviors. In addition, changes in immigrants’ health status are more apt to be associated with higher levels of acculturatio in the second and third generations. Limited awareness of obesity and health issues were related to obesity. With such limited awareness, family members might ignore the importance of PA.
- Other studies have indicated that socio-environmental factors might increase the likelihood of participation in PA among Chinese American children.
- Chinese culture and norms may shape parents’ roles differently, as compared to their western counterparts. Chinese families place their children’s academic performance as the top priority; for example, parents may not support participation in PA until all academic assignments and household responsibilities are completed. In such cases, children might have less chance and time to be engaged in PA.

Conclusion

Deteriorants at multiple levels influence the extent to which children with ASD engage in PA and exercise. At the same time, culture may be an important factor that influences engagement in PA. More research is needed in this area. Applying the social-ecological model and community-based programs of research might help us to better understand and conduct health challenges among Chinese-American children with ASD and their families.
