Abstract
67 year-old female with a history of rheumatoid arthritis (RA) and pulmonary hypertension (PH) presented for urgent C4-C5 anterior discectomy and C3-C6 posterior fusion for cervical subluxation. C-spine MRI showed severe cord impingement. The patient was brought to the operating room with minimal sedation to avoid exacerbation of PH. The radial artery was inaccessible due to flexion deformities, thus a brachial arterial line was placed. Awake fiberoptic intubation was performed with dexmedetomidine, followed by demonstration of movement of all four extremities. The anesthesia was maintained with dexmedetomidine and desflurane. The anterior and posterior portions of the procedure were performed uneventfully with no change in baseline somatosensory evoked potentials (SSSEP) and motor evoked potentials (MEP). The patient was extubated at the end of the case and was followed in the intensive care unit (ICU) and was discharged to rehabilitation in good condition.

Pulmonary Hypertension
PH is a life-threatening disease with a complex pathophysiology. The most recent classification was established in 2008. The 5 main categories are: (1) pulmonary arterial hypertension, (2) pulmonary venous hypertension due to left heart disease, (3) PH associated with lung disease, (4) chronic thromboembolic PH, and (5) PH with unclear multifactorial mechanisms. All pathways eventually lead to an altered vascular endothelium and smooth muscle function through cellular remodeling. Therapy is focused on improving hemodynamics, quality of life, and survival. The most important predictor of survival in PH is RV function.

Discussion
Patients with PH have markedly increased morbidity and mortality in the perioperative period. Preoperatively, thorough evaluation and risk assessment are necessary. Any chronic medical treatment should be continued until surgery. The intraoperative goal is to maintain adequate preload, systemic vascular resistance and contractility in order to allow the RV to maintain cardiac output. Acute on chronic increases in pulmonary vascular resistance (PVR) during the perioperative period can be caused by hypoxia, hypercarbia, acidosis, hypothermia, pain and anxiety. Early recognition and reversal of these causes could be life saving. This increase in RV afterload translates to increased RV transmural pressures leading to lack of perfusion of the RV myocardium through systole and diastole and ultimately acute decompensation. In contrast, hypotension and decreased preload should be aggressively treated to avoid decreased RV coronary perfusion and loss of the contribution of the interventricular septum to RV ejection.

Intraoperative treatment modalities for acute RV failure include IV vasodilators which may worsen hypotension, milrinone which can improve contractility, inhaled nitric oxide, inhaled or IV prostacyclin. Given its favorable sedative and analgesic properties together with its limited effects on pulmonary and respiratory function, there is growing evidence that dexmedetomidine can be used in PH patients.

Background

Past Medical History:
67 year-old female with a history of rheumatoid arthritis (RA) and pulmonary hypertension (PH) presented for urgent C4-C5 anterior discectomy and C3-C6 posterior fusion for cervical subluxation.

Rheumatoid Arthritis
The atlanto-axial joint is commonly affected in RA, causing atlanto-axial subluxation. Subaxial subluxation which occurs below C2 leads to earlier symptoms of nerve compression. Temporomandibular joint (TMJ) involvement may cause limitation of mouth opening and render direct laryngoscopy impossible. Fiberoptic intubation has improved the safety of airway management in surgical patients with RA. Where intubation is anticipated to be difficult because of cervical instability or a reduction in neck movement, an awake fiberoptic intubation and positioning of the C-spine is highly recommended.

Long term steroid therapy causes adrenal suppression, vasculitis, thin and fragile skin, which can render intravenous (IV) access difficult. The radial artery may be inaccessible because of flexion deformities of the wrist joint. Central venous catheters may be difficult to insert because of limited neck movement.

Medications:
- leflunomide
- sildenafil
- methylprednisolone
- Ambrisentan
- diclofenac
- pantoprazole
- home oxygen

Allergies:
- Succinylcholine, morphine

Imaging:
- Preoperative MRI demonstrating anterolisthesis of C4 on C5 causing moderately severe central canal stenosis and cervical spinal cord impingement
- Postoperative MRI revealing surgical changes, improved anatomical alignment, improved canal dimensions at C4-C5
- Post-operative c-spine x-ray demonstrating extensive anterior and posterior surgical hardware

Risks:
- Severe PH, advanced RA and scleroderma, chronic steroid therapy, chronic renal insufficiency (CRI), pseudocholinesterase deficiency

Surgical Treatment:
Surgical treatment for RA patients with cervical spine disease is challenging. The atlanto-axial joint is commonly affected in RA, causing atlanto-axial subluxation. Subaxial subluxation which occurs below C2 leads to earlier symptoms of nerve compression. Temporomandibular joint (TMJ) involvement may cause limitation of mouth opening and render direct laryngoscopy impossible. Fiberoptic intubation has improved the safety of airway management in surgical patients with RA. Where intubation is anticipated to be difficult because of cervical instability or a reduction in neck movement, an awake fiberoptic intubation and positioning of the C-spine is highly recommended.

Long term steroid therapy causes adrenal suppression, vasculitis, thin and fragile skin, which can render intravenous (IV) access difficult. The radial artery may be inaccessible because of flexion deformities of the wrist joint. Central venous catheters may be difficult to insert because of limited neck movement.
