Abstract

**Background:** Diadenosine tetraphosphate (Ap4A), a constituent of platelet dense granules, and its P1,P4-dithio and/or P2,P3-chloromethylene analogs, inhibit adenosine diphosphate (ADP)-induced platelet aggregation. We recently reported that these compounds antagonize both platelet ADP receptors, P2Y1 and P2Y12. The most active of those analogs, diadenosine 5',5''-P1,P4-dithio-P2,P3-chloromethylenetetraphosphate, exists as a mixture of 4 stereoisomers.

**Objective:** To separate the stereoisomers of compound 1 and determine their effects on platelet aggregation, platelet P2Y1 and P2Y12 receptor antagonism, and their metabolism in human plasma.

**Methods:** We separated the 4 diastereomers of compound 1 by preparative reversed-phase chromatography, and studied their effect on ADP-induced platelet aggregation, P2Y1-mediated changes in cytosolic Ca2+, P2Y12-mediated changes in VASP phosphorylation, and metabolism in human plasma.

**Results:** The inhibition of ADP-induced human platelet aggregation and human platelet P2Y12 receptor, and stability in human plasma strongly depended on the stereo-configuration of the chiral P1- and P4-phosphorothioate groups, the Sβ,Sβ diastereomer being the most potent inhibitor and completely resistant to degradation in plasma, and the Rβ,Rβ diastereomer being the least potent inhibitor and with the lowest plasma stability. The inhibitory activity of Sβ,Rβ diastereomers depended on the configuration of the pseudo-asymmetric carbon of the P2,P3-chloromethylene group, one of the configurations being significantly more active than the other. Their plasma stability did not differ significantly, being intermediate to that of the Sβ,Sβ and the Rβ,Rβ diastereomers.

**Conclusions:** The presently-described stereoisomers have utility for structural, mechanistic, and drug development studies of dual antagonists of platelet P2Y1 and P2Y12 receptors.

Introduction

Platelets express two G-protein-coupled P2Y (nucleotide activated) receptors, P2Y1 and P2Y12 [1]. Both receptors are activated by adenosine 5'-diphosphate (ADP) and play essential and mutually dependent roles in the process of platelet activation and aggregation [1]. Gq coupled P2Y1 activates the beta-isofrom of phospholipase C (PLCβ) and causes inositol 1,4,5-trisphosphate (IP3)-mediated increase in intracellular calcium levels, mainly by calcium release from intracellular stores. P2Y1 activation initiates ADP-induced platelet aggregation and results in platelet shape change [1]. However, without P2Y12 activation, the result is a small and reversible platelet aggregation. Gi-coupled P2Y12 inhibits adenylyl cyclase, thereby stimulating phosphatidylinositol-3 kinase (PI3K) activity. Reduced cAMP levels further reduce cAMP dependent protein kinase A phosphorylation of vasodilator-stimulated phosphorylase (VASP), a modulator of platelet cytoskeletal proteins [2]. Functionally this results in potentiation of platelet secretion, and amplification and stabilization of the

Introduction

Platelets express two G-protein-coupled P2Y (nucleotide activated) receptors, P2Y1 and P2Y12 [1]. Both receptors are activated by adenosine 5'-diphosphate (ADP) and play essential and mutually dependent roles in the process of platelet activation and aggregation [1]. Gq coupled P2Y1 activates the beta-isofrom of phospholipase C (PLCβ) and causes inositol 1,4,5-trisphosphate (IP3)-mediated increase in intracellular calcium levels, mainly by calcium release from intracellular stores. P2Y1 activation initiates ADP-induced platelet aggregation and results in platelet shape change [1]. However, without P2Y12 activation, the result is a small and reversible platelet aggregation. Gi-coupled P2Y12 inhibits adenylyl cyclase, thereby stimulating phosphatidylinositol-3 kinase (PI3K) activity. Reduced cAMP levels further reduce cAMP dependent protein kinase A phosphorylation of vasodilator-stimulated phosphorylase (VASP), a modulator of platelet cytoskeletal proteins [2]. Functionally this results in potentiation of platelet secretion, and amplification and stabilization of the
aggregation response. There is a complex interplay between P2Y1 and P2Y12, and co-activation of both receptors, or the signaling pathways they trigger is necessary for full platelet aggregation to take place [3].

Diadenosine 5',5''-tetraphosphate (Ap4A, Figure 1) is the most important member of the group of dinucleoside polyphosphates. It is found in a variety of cells, is secreted extracellularly, and is involved in the regulation of variety of intra- and extracellular physiological functions [4]. In platelets Ap4A is stored in dense granules and is therefore released along with ADP and ATP upon platelet activation [5]. Early studies of diadenosine polyphosphates found that diadenosine triphosphate induces platelet aggregation and that Ap4A antagonizes this effect [6]. It is now well known that Ap4A inhibits ADP-induced platelet activation [7], and a number of Ap4A analogs with modifications in the tetraphosphate chain have been synthesized and studied with the aim to improve on this effect and to increase the biological stability [8–10]. We recently reported that Ap4A and its P1- and/or P4-thio, and P2,P3-chloromethylene analogs inhibit platelet aggregation by targeting both P2Y1 and P2Y12 receptors [11,12]. The most potent of these analogs for inhibition of platelet aggregation, diadenosine 5',5''-P1,P4-dithio-P2,P3-chloromethylenetetraphosphate, (compound 1, Figure 1) [8,12] has thio substitutions at the two terminal phosphate groups, which render the corresponding phosphorus atoms (P1 and P4) chiral. This, together with the pseudo-asymmetric carbon atom of chloromethylene group between P2 and P3 [13] gives rise to 4 stereoisomers for compound 1 [14] (See Discussion for details).

Phosphorothioate stereoisomers, in general, differ significantly in their substrate or ligand properties [15,16], a fact which has been used extensively for various mechanistic studies [17]. Considering that platelet P2 receptors may exhibit stereoselectivity for the stereoisomers of 1 we preparatively separated its four diastereomers and studied their actions on ADP-induced human platelet aggregation, human platelet P2Y1 and P2Y12 receptors antagonism, and their stability and metabolism in human plasma. We found that the stereo configuration at P1 and P4 has significant effects on platelet aggregation, P2Y12 antagonism and plasma stability, and lesser effect on P2Y1 antagonism. Compounds with Sp configuration at both P1 and P4 have the highest platelet aggregation and P2Y12 inhibitory potency and highest stability in plasma.

Materials and Methods

Materials

Compound 1 was prepared as previously described [18]. Adenosine 5''-(P1-thio-P2,P3-chloromethylenetriphosphate), compound 2 was isolated as a minor byproduct during the synthesis of 1 and was characterized by H1 and 31P NMR and liquid chromatography-mass spectrometry (LCMS). Adenosine 5''-thiomonomophosphate (tihoAMP), MRS2179, probenecid, adenosine 5''-(β,γ-methylenetriphosphate) (β,γ-CH2-ATP), ethylene glycol tetracetic acid (EGTA) and apyrase (grade VII) were purchased from Sigma-Aldrich (St. Louis, MO), D-Phenylalanil-L-prolyl-L-arginine chloride methyle ketone (PPACK) was purchased from Calbiochem (La Jolla, CA), FLUO-4 was from Invitrogen (Carlsbad, CA), ADP from Bio/Data (Horsham, PA), CD41-phycerythrin (PE)-Cy5 from Beckman Coulter (Fullerton, CA). The VASP phosphorylation kit was purchased from BioCytex (Marseilles, France).

Figure 1. Chemical structure and stereo-configuration of the stereoisomers of diadenosine 5',5''-P1,P4-dithio-P2,P3-chloromethylenetetraphosphate (compound 1), and of adenosine 5''-(P1-thio-P2,P3-chloromethylenetriphosphate), (compound 2). Rp and Sp designate the absolute configuration of chiral P1- and P4-phosphorothioates; r and s, the absolute configuration of the pseudo-asymmetric carbon of the P2,P3-chloromethylene group in compound 1; R and S, the absolute configuration of the chloromethylene group in compound 2. Ade, 5''-adenosyl; N.A., Not Asymmetric.
doi:10.1371/journal.pone.0094780.g001

Separation of the diastereomers of compound 1

Analytical separation of the diastereomers of compound 1 by reversed-phase high performance liquid chromatography (HPLC) has been described [14]. In the present work we used a modification of this method, utilizing a XBridge RP C18 3.5 μm, 4.6×150 mm column with a 4.6×10 mm guard column (Waters Inc., Waltham, Mass. USA), and a binary linear gradient from 100% of mobile phase A to 35% of mobile phase B in A for 35 min (A was 20 mM potassium phosphate buffer with pH 7, and B was 20% methanol in A) at 1 ml/min, 30°C column temperature, and UV detection at 260 nm.

Preparative separation was done on an XBridge C18 5 μm, 20×250 mm preparative column at 20 ml/min, all other condi-
tions being the same as at the analytical runs. The fractions containing the separated diastereomers were pooled and concentrated under vacuum, and then desalted on the same column using volatile triethylammonium bicarbonate (TEAB) buffer, and a 15 min gradient from 0.2 M TEAB to 50% methanol in 0.2 M TEAB at 20 mL/min. The desalted fractions were evaporated under vacuum and the residual TEAB buffer was removed by repeated evaporation from methanol. Finally each diastereomer was converted to the sodium salts by passing through a column of Dowex W50X2 (5 × 20 mm) in the sodium form, followed by lyophilization. The isolated diastereomers were characterized by proton and phosphorous NMR and by mass spectrometry. Stock solutions (10 mM) in water were prepared using molar absorptivity of 20.2 mM−1cm−1 at 260 nm [8], and were stored frozen at −80°C.

Ethics Statement
This study was approved by the University of Massachusetts Medical School Institutional Review Board (IRB). Written IRB-approved informed consent was obtained prior to blood collection.

Blood collection and sample preparation
Human blood samples were taken from healthy volunteer donors free from aspirin or other non-steroidal anti-inflammatory drugs for more than 7 days. Blood was drawn from antecubital veins into tubes containing 3.2% sodium citrate. For platelet aggregation assays the blood was centrifuged at 110 × g for 12 minutes, and platelet-rich plasma (PRP) was immediately removed. Centrifugation at 1650 × g for 10 minutes was to obtain platelet-poor plasma (PPP).

ADP-induced platelet aggregation
The 96-well microplate method for the detection of ADP-induced platelet aggregation and the concentration dependence of its inhibition by the tested compounds was used as previously described [11,12], thereby avoiding the problem of platelet aging [19,20]. In brief, PRP at 37°C was added to a pre-warmed 96-well microplate containing ADP (3 μM final concentration) and test compounds (various concentrations) or vehicle (10 mM Hepes, 0.15 M NaCl, pH 7.4). Light transmission at 580 nm was recorded immediately and at 11 second intervals for 6 min at 37°C with intermittent programmed shaking of the plate in a Molecular Devices microplate reader. Within each experiment all samples were run in duplicate and each experiment was repeated 3–5 times with PRP from different donors.

P2Y12-mediated vasodilator-stimulated phosphoprotein (VASP) phosphorylation assay
VASP phosphorylation was measured by flow cytometry using a BioCytex kit, essentially according to the manufacturer’s recommendations, except that a small volume of the test compound solution or vehicle (HEPES-saline) was added to each assay tube as previously described [11,12]. Analysis was performed in a FACSCalibur (Becton Dickinson) flow cytometer.

P2Y12-mediated cytosolic Ca2+ increase assay
ADP-dependent, P2Y12-mediated increase in platelet cytosolic Ca2+ was measured by detecting changes in FLUO-4 fluorescence as previously described [11,12]. In brief, citrated whole blood was added to a loading solution consisting of 5 μM FLUO-4, CD41-PE-Cy5 and 1 mM probenecid, and the mixture was incubated for 30 minutes at room temperature. Samples were diluted 36-fold in 10 mM HEPES, 0.15 M NaCl, pH 7.4 and analyzed in a FACSCalibur flow cytometer. After obtaining a 30 second baseline recording, the acquisition was paused, and 60 μL of ADP (3 μM final concentration) and test compound solutions at various concentrations or ADP plus vehicle (HEPES-saline) were quickly added, the sample mixed, and the acquisition resumed (total pause time less than 10 seconds). FLUO-4 fluorescence before and after addition of ADP (3 μM final concentration) and test compound solutions was monitored. The mean FLUO-4 fluorescence of the baseline 30-second interval and of 10-second post-stimulant intervals was calculated. The cytosolic Ca2+ increase was calculated as the ratio of the maximal post-stimulant FLUO-4 fluorescence to the baseline FLUO-4 fluorescence. The percent inhibition of ADP-induced Ca2+ increase due to the addition of the test compounds was calculated relative to 3 μM ADP plus vehicle (HEPES-saline).

Stability and metabolism in plasma
Frozen, pooled, heparin-anticoagulated human plasma (BioReclamation, Westbury, NY, catalog # HMPLNAHP) was thawed upon arrival, aliquoted (2.5 mL) in sterile polypropylene vials, re-frozen in dry ice, and stored at −20°C. At the time of testing the plasma aliquots were thawed and incubated at 37°C for 10 minutes. Test compound, 25 μL of 10 mM solution in water (100 μM final concentration) was added, the sample was mixed briefly, and incubated at 37°C. Aliquots (100 μL) were taken at the indicated times, mixed with 35% HClO4 (8 μL), and centrifuged (10 min, 13 000 x g). Forty μL supernatant were removed, mixed with 160 μL of 50 mM K2CO3, and centrifuged (15 min, 13 000 x g). Supernatant, 150 μL was removed for HPLC analysis. The chemical stability of the test compounds under the incubation and work up conditions was controlled by incubation with heat-inactivated (10 minutes at 95°C) plasma. Plasma incubation without test compound addition was used for method specificity control. The external standard calibration was done using plasma samples, spiked with test compounds, and processed without incubation. The extraction efficiency was evaluated by analysis of the calibration samples relative to the analysis of standard samples in mobile phase, and was above 90%. The main metabolites, the diastereomers of compound 2 (Figure 1) and thioAMP, were identified by LCMS analysis of incubation mixtures, and confirmed by analysis of heat-inactivated plasma samples spiked with thioAMP and synthetic compound 2.

Statistical analysis
The results were analyzed using GraphPAD Prism software, version 4.00 for Windows (GraphPad Software, San Diego, CA). All data are expressed as mean followed by 95% confidence interval (95% CI). Student’s t-test was used to determine statistical significance when two groups of data were compared. One-way ANOVA and Bonferroni’s multiple comparison tests were used when three or more groups of data were compared. The rate constants for degradation in plasma and the associated half-lives were estimated by a non-linear fitting of first order elimination model to the chromatographic peak areas.

Results
Separation of diastereomers
Excellent separation of the diastereomers of compound 1 was achieved with 20 mM potassium phosphate buffer at very low (1–7%) methanol content on a C18 column (Figure 2A). The optimal pH of the buffer was from 7 to 8. The peak shape quickly deteriorated at pH values below 6. This method scaled up well on preparative XBridge C18 5 μm column (25×250 mm). After
desalting and conversion to their sodium salts, 1.7, 3.3, 3.8, and 2.4 mg of diastereomers 1.1, 1.2, 1.3, and 1.4, respectively, were prepared. The purity of each diastereomer was above 95% by analytical HPLC (Figure 2B). By mass spectroscopy, the isolated diastereomers were all identical and indistinguishable from the racemic mixture (data not shown). Characterization by phosphorous NMR showed distinct resonance profiles in the P1,P4 and P2,P3 regions for each of the isolated diastereomers (Figure 3) consistent with their high purity. The most significant differences in the proton NMR spectra were in the resonances of the proton of the monochloromethylene group (see structure in Figure 1), which, due to the two bond coupling to P2 and P3, were observed as characteristic triplets ($\Delta J_{P-H} = 17.3–17.7$ Hz) at 4.675 (1.1), 4.454 (1.2), 4.825 (1.3), and 4.525 (1.4) ppm.

The absolute configurations of the phosphorothioate groups of the four diastereomers of compound 1 (Figs. 1 and 2) have already been assigned [14] by using snake venom phosphodiesterase digestion (See Discussion section for details).

Inhibition of ADP-induced platelet aggregation

Figure 4A shows the dose response curves, determined in parallel, of the four diastereomers of compound 1 for inhibition of 3 μM ADP-induced platelet aggregation. The IC50s (listed in Table 1) for diastereomers 1.1 and 1.3 were not significantly different from each other. The IC50s for diastereomers 1.2 and 1.4 also did not differ significantly from each other, but were both significantly higher ($p<0.0001$, F-test) than those for 1.1 and 1.3.

Antagonism of platelet P2Y12-mediated, ADP-induced decrease in VASP phosphorylation

The relative potency of the four diastereomers to inhibit platelet P2Y12 receptors was tested by their ability, at a single concentration of 10 μM, to inhibit the ADP-induced decrease of VASP phosphorylation, an index of platelet P2Y12 receptor activation [11,12]. The percent inhibitions are shown in Figure 4B and Table 1. Compared with diastereomer 1.1, diastereomer 1.4 was significantly less potent ($p<0.01$, Bonferroni’s multiple comparison test), and did not differ significantly from each other. The order of potency was 1.1 > 1.3 > 1.2 > 1.4.

Antagonism of platelet P2Y1-mediated, ADP-induced increase in cytosolic Ca2+

The relative potency of the individual diastereomers of compound 1 to inhibit platelet P2Y1 receptors was evaluated at the single concentration of 10 μM by their ability to reduce 3 μM ADP-induced intracellular Ca2+ increase due to P2Y1-mediated Ca2+ release from intraplatelet stores. The percent inhibitions are shown in Figure 4C and Table 1. Compared with diastereomer 1.1, diastereomer 1.4 was significantly less potent for inhibition of
platelet P2Y1 function \( p < 0.05, n = 6 \), Bonferroni’s multiple comparison test) while \( 1.2 \) and \( 1.3 \) did not differ significantly from \( 1.1 \). The order of potency was \( 1.2 > 1.1 > 1.3 > 1.4 \).

Metabolism in human plasma

Although compound 1 is very stable in human plasma, by using very long incubation times we were able to observe clear

Figure 5. Stability and metabolism of the four diastereomers of compound 1 in human plasma at 37 °C. t1/2: half-life of first order elimination. For other abbreviations, see Figure 1. doi:10.1371/journal.pone.0094780.g005

differences in the rate of degradation and the type of degradation products of its diastereomers (Figure 5). Diastereomer 1.4 degraded to thioAMP with a half-life (t1/2) of 8.1 hours. Diastereomers 1.2 and 1.3 degraded with almost equal rates (t1/2 17.9 and 18.5 hours, respectively) giving equal amounts of thioAMP and two different stereoisomers of the triphosphate 2, which were resistant to further hydrolysis. Diastereomer 1.1 was completely stable in human plasma, with no loss after 96 hours incubation at 37°C. In fact we did not observe measurable degradation of this diastereomer even after incubation for 6 days at 37°C (data not shown). Also, control incubation of the diastereomeric mixture of 1 at 37°C with heat denatured human plasma for 6 days showed no decomposition, demonstrating the remarkable chemical stability of compound 1. The overall order of stability of the four diastereomers of compound 1 in human plasma was 1.1>1.2=1.3>1.4.

Discussion

Stereoisomers of compound 1 and their absolute configuration assignment

The absolute configuration of a phosphorous atoms containing 4 different substituents is designated, according to Ingold-Kahn-Pregol notation, as R or S [21]. The subscript “P” indicates that this absolute configuration applies to an asymmetric phosphorous, and not to a carbon atom. The stereochemical character of the chloromethylene group in compound 1 depends on the absolute configuration at P1 and P4. When P1 and P4 have the same configuration (RPSP, SPSP) the carbon atom of the chloromethylene group in compound 1 is identical to RPStP because of the symmetry of the molecule relative the chloromethylene group, Figure 1). All those stereoisomers are diastereomeric to each other because of the chiral character of the ribose moiety. Blackburn et al. [14,22] used digestion with snake venom phosphodiesterase (SVP), and the well established resistance of phosphorothioates in Sp configuration to hydrolysis by this enzyme [23,24] to assign the absolute configurations of the four diastereomers of compound 1 and its closely related monofluoromethylene analog in the order of their elution (Figure 2) as: 1.1, SpSpC, 1.2, SpRSP or SpRSp; 1.3, SpRSP or SpSpP, and 1.4, RpRsp. These assignments are also in agreement with the well known observation that Sp phosphorothioates elute earlier the Rp isomers [23,24]. The SVP digestion method does not allow for the determination of the absolute configuration of the pseudo-asymmetric carbon atom between P2 and P3.

Inhibition of ADP-induced platelet aggregation and platelet P2Y1 and P2Y12 receptors

Well-defined differences in inhibition of ADP-induced platelet aggregation and platelet P2Y1 and P2Y12 antagonist properties of the four diastereomers of compound 1 were observed (Figure 4 and Table 1). The diastereomers of compound 1 could be separated into two groups based on their potency for inhibition of platelet aggregation: 1.1, 1.3 and 1.2, 1.4. The differences between the IC50s within each pair are not statistically significant, but between the pairs the differences are statistically significant, 1.1 and 1.3 being significantly more active than 1.2 and 1.4. This same order of potency was observed for the antagonist activity of the diastereomers toward P2Y12 (Figure 4B), where 1.1 and 1.3 are significantly more active than 1.2 and 1.4. In contrast, 1.2 inhibited P2Y1 with potency similar to that of 1.1 and 1.3 and greater than that of 1.4 (Figure 4C), yet it had reduced potency for inhibition of platelet aggregation (Figure 4A). Compound 1.4, showed significantly reduced antagonist activity towards both P2Y1 and P2Y12, and had the highest IC50 for inhibition of platelet aggregation.

Taken together, these results suggest that for optimal platelet aggregation and platelet P2Y1 and P2Y12 receptor inhibition at
least one of the P^1 and P^4 phosphorothioates needs to be in the Sp configuration. Structurally, 1.2 and 1.3 differ only in the configuration of the carbon atom of the chloromethylene group, but differ significantly in their ability to antagonize P2Y_{12}. Because the absolute configuration of this carbon atom is assigned arbitrarily to r or s, we cannot presently ascertain the absolute configuration of the chloromethylene group that favors P2Y_{12} antagonism.

In the case of P2Y_{1}, 1.4 (R^pR^p configuration) is the least active, yet the difference between all diastereomers, and especially between 1.2 and 1.3, is less pronounced if compared with the differences in their activity observed for P2Y_{12} receptors. Even though chiral phosphorothioate nucleotides have been extensively used as probes for structural and mechanistic studies of enzymes and receptors [15–17], and the question of molecular recognition of P2Y_{12} receptors has been addressed in numerous works (e.g., see [25,26] and references cited therein), to the best of our knowledge the question of P2Y_{12} stereoselectivity has not been addressed. Major et al. [27] studied P2Y_{1} receptors stereoselectivity using the diastereomers of 5'-thioATP, 5'-thio-2-thiomethyl-ATP, and 5'-thio-2-chloroATPs as agonists of human P2Y_{1} receptors in HEK cells. The diastereomers with Sp configuration displayed 8–20 fold higher agonist activity than the R^p diastereomers. Assuming a similar mode of binding and identical binding sites for ATP and Ap_{p}A analogs, those results would corroborate our conclusions for the preference of P2Y_{1} receptors for the Sp configuration at P^1.

In the present study we observed better correlation between P2Y_{12} inhibition and platelet aggregation inhibition than between P2Y_{1} inhibition and platelet aggregation inhibition for the four diastereomers of compound 1. Yet, in our opinion, this observation cannot be used to discount a possible contribution of P2Y_{1} inhibition to the overall platelet aggregation inhibition by these compounds, especially taking into account the relatively small number of binding sites of the P2Y_{1} receptors on the platelet surface [28], and further studies will be necessary to shed light on the relative contribution of the inhibition of each of the receptors.

Stereoselectivity in the plasma metabolism of the diastereomers of compound 1

Because of the important physiological functions of dinucleoside polyphosphates their intra- and extracellular levels are tightly regulated [29]. Extracellular dinucleoside polyphosphates are hydrolyzed by ecto-nucleotide pyrophosphatase/phosphodiesterases 1–3 (NPP1, PC-1; NPP2, autotoxin; NPP3, Gp130) [30]. Despite the important physiological role of NPP1-3, little is known about their stereospecificity. Koziolkiewicz et al. [31] determined that 3'-exonuclease present in human plasma degrades phosphorothioate oligonucleotides with the Rp configuration, whereas the Sp configuration is resistant to hydrolysis. More recently, Wójcik et al. [32] showed that the enzyme responsible for this action is NPP1 (PC-1). The present results show that the degree of the stabilization due to the thio modification depends significantly on its stereo configuration, and that the phosphorothioate group in the Sp configuration is resistant to the hydrolytic action of those enzymes. Thus compound 1.4, having both P^1 and P^4 in the Rp configuration was the least stable diastereomer, presumably being degraded first to one mole of thioAMP and one mole of compound 2 in the Rp configuration (actually, equal amount of diastereomers 2.3 and 2.4, see Figure 1). Both 2.3 and 2.4 have a phosphorothioate group in the Rp configuration, and are further quickly degraded to thioAMP and chloromethylene-4p-phosphonate. Diastereomers 1.2 and 1.3, which both have one phosphorothioate group in the Rp and one in the Sp configuration, were hydrolyzed about 2 times slower than 1.4 to equimolar amount of thioAMP and two stereo isomers of compound 2, which were stable to further hydrolysis. This suggests that both 1.2 and 1.3 are hydrolyzed at the thio phosphate group in the Rp configuration, giving the SpS and SpR isomers of 2 (2.1 and 2.2, Figure 1), which both have their phosphorothioate group in the Sp configuration, and resist further hydrolysis. Finally, 1.1, having both P^1 and P^4 phosphorothioate groups in the Sp configuration did not show signs of hydrolysis even after very long (up to 6 days) incubations in human plasma.

The physiologically important function of the ecto-nucleotide pyrophosphatase/phosphodiesterase enzymes in regulating and spatially modulating various purinergic signaling pathways, and their value as therapeutic targets have been increasingly realized [33,34], which makes the development of inhibitors or high affinity probes of the NPP class an important research direction. Compound 1.1 could be utilized as a convenient starting point for that purpose. Our observation that 1.1 was completely resistant to plasma degradation even after very long incubations opens the possibility of crystallizing its complex with NPPs, thus providing additional information for this important class of enzymes.

P2Y_{12} is among the most important targets of antiplatelet drugs in current use and under development [35]. The potential of P2Y_{1} as a target for new antiplatelet drugs, or agents regulating the vascular inflammation process has been recognized [36]. The information in this study can be used to aid in elucidating the structure and the mode of action of these targets, and in the design of new inhibitors of scientific and/or therapeutic interest — specifically inhibitors of both P2Y_{1} and P2Y_{12}.
