Watershed Infarcts in Acute Hypereosinophilia

Jiaying Zhang, Anthony Izzo, and Majaz Moonis
Department of Neurology
University of Massachusetts Medical School, Worcester, MA

A 79-year-old woman presented with generalized weakness, encephalopathy, and non-ST elevation myocardial infarction. Complete blood cell count showed elevated white blood count of 23.7/mm$^3$ with 67% eosinophils and absolute eosinophil count of 15.9/mm$^3$. Initial MRI revealed punctate scattered infarcts throughout cerebral and cerebellar hemispheres and the brainstem within watershed territories. There were no episodes of hypotension. Her neurological exam worsened the next day with coma and extensor posturing. Repeat MRI within 24 hours showed worsening with innumerable infarcts.

While neurological involvement is common, it is under-recognized in hypereosinophilic syndrome.$^1$ Acute watershed infarction is either due to in-situ thrombus formation from hyperviscosity or thromboembolism from a distant source.$^2$
