Mitochondrial Stress Restores the Heat Shock Response and Prevents Proteostasis Collapse during Aging

Graphical Abstract

Highlights

- Impaired mitochondrial function suppresses the programmed repression of the HSR
- Mitochondria regulate the collapse of stress resistance and cytosolic proteostasis
- The effect of mitochondria on stress resistance and proteostasis is regulated by HSF-1
- Mitochondrial “tuning” maintains cytoplasmic proteostasis without affecting fecundity

In Brief
Using the nematode Caenorhabditis elegans, Labbadia et al. demonstrate that low levels of mitochondrial stress caused by exposure to RNAi or xenobiotics can restore HSF-1 function with age, thereby maintaining cytosolic proteostasis, enhancing stress resistance, and prolonging healthspan, all without detrimental effects on development or reproduction.

SUMMARY

In Caenorhabditis elegans, the programmed repression of the heat shock response (HSR) accompanies the transition to reproductive maturity, leaving cells vulnerable to environmental stress and protein aggregation with age. To identify the factors driving this event, we performed an unbiased genetic screen for suppressors of stress resistance and identified the mitochondrial electron transport chain (ETC) as a central regulator of the age-related decline of the HSR and cytosolic proteostasis. Mild downregulation of ETC activity, either by genetic modulation or exposure to mitochondria-targeted xenobiotics, maintained the HSR in adulthood by increasing HSF-1 binding and RNA polymerase II recruitment at HSF-1 target genes. This resulted in a robust restoration of cytoplasmic proteostasis and increased vitality later in life, without detrimental effects on fecundity. We propose that low levels of mitochondrial stress regulate cytoplasmic proteostasis and healthspan during aging by coordinately maintaining the long-term activity of HSF-1 with conditions preclusive to optimal fitness.

INTRODUCTION

Old age is the primary risk factor for many human diseases, but the overarching principles and molecular mechanisms that drive aging remain poorly understood (López-Otin et al., 2013). Aging has long been thought of as a stochastic process that is characterized by the gradual accumulation of cell damage. However, recent evidence suggests that aging arises, at least in part, from programmed events early in life that promote reproduction (Ben-Zvi et al., 2009; David et al., 2010; Reis-Rodrigues et al., 2012; Walther et al., 2015).

Proteostasis is routinely maintained through the activity of constitutive and inducible stress response pathways. Among these, the transcription factor HSF-1 promotes the expression of molecular chaperones and enhances protein-folding capacity in the cytosol and nucleus through the heat shock response (HSR). During C. elegans adulthood, the HSR undergoes rapid repression as animals commence reproduction, thereby leaving cells vulnerable to environmental stress and proteostasis collapse well before overt signs of aging are distinguishable (Labbadia and Morimoto, 2015a; Shemesh et al., 2013). This suggests that precise regulatory switches actively repress the HSR early in life as part of programs that promote reproduction at the cost of proteostasis (Labbadia and Morimoto, 2015a). However, it remains unclear which molecular and physiological processes drive the repression of the HSR and the loss of stress resistance in adulthood, how environmental factors influence this, and whether maintenance of proteostasis can be uncoupled from reduced fecundity.

To this end, we performed an unbiased genetic screen to identify genes whose knockdown maintains resistance to thermal stress and prevents repression of the HSR in reproductively active adults. We identified the mitochondrial electron transport chain (ETC) as a robust determinant of the timing and severity of the decline in the HSR and show that mild mitochondrial stress increases HSF-1 binding at target promoters, maintains the HSR, and preserves proteostasis in reproductively active animals. These beneficial effects were achieved without the severe physiological defects typically associated with impaired mitochondrial function, suggesting that modulation of mitochondrial activity is a physiologically relevant determinant of the timing of repression of the HSR and cytosolic proteostasis collapse with age.

RESULTS

Complex IV Inhibition Increases Stress Resistance and Maintains the HSR with Age

The activity of the HSR and thermal stress resistance decline dramatically between day 1 and day 2 of adulthood in C. elegans (Labbadia and Morimoto, 2015a). To identify...
Figure 1. Complex IV Inhibition Increases Stress Resistance and Maintains the HSR in Reproductively Mature Adults

(B) Thermorecovery of L4440 or F29C4.2(RNAi)-treated worms 48 hr following heat shock (HS) (33°C, 6 hr) on solid NGM plates at different days of adulthood. Related survival curves can be found in Figure S1.

(D–H) Relative expression of hsp-6 (D), hsp-4 (E), hsp-70(C12C8.1) (F), hsp-70(F44E5.4) (G), and hsp-16.11 (H) relative to the housekeeping genes rpb-2 and cdc-42 in L4440 or F29C4.2(RNAi) treated animals following HS (33°C, 30 min) at different days of adulthood.

(legend continued on next page)
pathways that control the collapse of stress resistance, we performed an unbiased genome-wide RNAi screen for genes whose knockdown maintained resistance to thermal stress in reproductive (day 2, 24 hr post-vulva formation) adults (Figure S1A). At day 1 of adulthood (4 hr post-L4 molt), ~80% of animals move vigorously 48 hr after heat shock (HS) (Figure 1A). In contrast, on day 2, only 20% of adult animals exhibit normal movement after HS (Figure 1A). We identified 11 genes (Figure 1A; Table S1) whose knockdown restored stress resistance to at least 50% on day 2 of adulthood. Of these, knockdown of F29C4.2 (a predicted cytochrome c oxidase subunit orthologous to human COX6C and previously identified in a parapat resistance screen; Kim and Sun, 2007) fully restored stress resistance (Figure 1A). F29C4.2(RNAi) increased stress resistance through day 7 of adulthood (Figure 1B) and was effective in conferring protection against normally lethal stress conditions (Figures 1C and S1B), thus demonstrating that F29C4.2 is a potent modifier of the decline in cellular robustness with age.

ETC disruption is associated with increased longevity and improved health through activation of the mitochondrial unfolded protein response (UPRmt) (Yun and Finkel, 2014). Consistent with this, F29C4.2(RNAi) significantly increased basal expression of the canonical UPR mt genes hsp-6 and hsp-60 on day 1 and day 2 of adulthood and strongly activated an hsp-6::gfp reporter (Figures S1C–S1E), F29C4.2(RNAi) also enhanced hsp-6 induction in response to HS on day 1 of adulthood and robustly maintained hsp-6 inducible expression therefrom (Figure 1D). These results indicate that F29C4.2(RNAi) constitutively activates and enhances the responsiveness of the UPRmt in adulthood, even before enhanced stress resistance is observed.

We next examined whether F29C4.2(RNAi) specifically augments the UPRmt or has effects on the HSR and the endoplasmic reticulum UPR (UPRER), which both decline early in adulthood (Labbadia and Morimoto, 2011; Taylor and Dillin, 2013). Basal expression of core cytosolic chaperones, canonical HSR genes, the ER inducible HSP70 homolog of the UPRER, and fluorescent reporters of the HSR or UPRER was not induced upon F29C4.2(RNAi) (Figures S1C–S1E). However, upon exposure to HS, the levels of hsp-4, hsp-70(C12C8.1), hsp-70(F44E5.4), and hsp-16.11 were maintained from day 2 through day 7 of adulthood by F29C4.2(RNAi) (Figures 1E–1H). In keeping with the enhanced HSR in day 2 adults, HSP-16 protein levels were also increased 2-fold in F29C4.2(RNAi) animals compared to L4440 controls following HS (Figure 1I).

Consistent with reports from other groups (Kim et al., 2016; Yoneda et al., 2004), our data demonstrate that ETC perturbation activates the UPRmt but does not constitutively activate the HSR or UPRER. Furthermore, we find that although F29C4.2(RNAi) results in activation of the UPRmt during adolescence, enhanced induction of cell stress response genes is only observed in reproductive adults, suggesting that ETC perturbation influences proteostasis-related pathways in a stage-specific manner.

Lifespan assurance and activation of the UPRmt are dependent on changes in ETC activity during development (Dillin et al., 2002; Rea et al., 2007; Durieux et al., 2011). Therefore, we exposed animals to F29C4.2(RNAi) at distinct larval stages and measured stress resistance in post-reproductive adults. Exposure to F29C4.2(RNAi) in early development (L1–L3 stage) was sufficient to fully maintain stress resistance through day 4 of adulthood, whereas stress resistance was not enhanced in animals placed on F29C4.2(RNAi) from the L4 or young adult stages onward (Figure 1J). These findings suggest that, like lifespan extension and activation of the UPRmt, the modulation of stress resistance with age is dependent on mitochondrial activity during development (Dillin et al., 2002; Rea et al., 2007; Durieux et al., 2011).

Disruption of Various Mitochondrial Pathways Enhances the HSR and Stress Resistance in Reproductively Mature Adults

Enhanced stress resistance is intimately linked to longevity, and it has been shown that RNAi of many mitochondria-associated genes extends lifespan (Bennett et al., 2014; Dillin et al., 2002; Houtkooper et al., 2013; Lee et al., 2003). Therefore, we asked whether F29C4.2 was unique in its ability to enhance the HSR and maintain stress resistance. In our primary screen, several other genes encoding proteins with mitochondrial function (cco-1, ncu-4, cyc-1, tomm-22, and mrps-5) were identified but filtered out due to effects on development and/or fecundity. We therefore exposed animals to RNAi against subunits of complex I, complex III, and complex IV or against genes integral to mitochondrial import or mitochondrial protein synthesis and assessed stress resistance in reproductively mature adults. In addition, animals were exposed to RNAi against the AAA metalloprotease coding gene spg-7, which is known to induce the UPRmt (Haynes et al., 2010; Yoneda et al., 2004). We corrected for developmental delay by assessing resistance to thermal stress in animals that were physiologically age matched (laying eggs for 24 hr prior to HS).

As expected, RNAi against all mitochondria-associated genes induced hsp-6 expression (≥1.5-fold) at day 2 of adulthood (Figure S2A), but not the basal expression of HSR genes (Figure S2C). Upon exposure to heat stress, RNAi against subunits of complexes I, III, and IV or against tomm-22 and mrps-5 significantly increased stress resistance in reproductively active adults to an extent similar to that observed for F29C4.2(RNAi) (Figures 2A and S2B). However, RNAi against dnj-21, tin-44, mrpl-1, mrpl-2, and spg-7 had little or no effect on stress resistance (Figures 2A and S2B). These data suggest...
Figure 2. Multiple Forms of Mitochondrial Perturbation Maintain Stress Resistance and Enhance the HSR in Reproductively Mature Adults

(A) Survival following HS (35°C, 4 hr) at standard chronological day 2 of adulthood or physiological day 2 (PD2) of adulthood (animals were allowed to develop longer before HS to correct for delayed onset of egg-laying) in worms grown on empty vector control (L4440) or RNAi against mitochondria associated genes. Heatmap is plotted as the mean survival at different days post-HS for each condition. Related survival curves can be found in Figure S2.

(legend continued on next page)
that stress resistance can be enhanced in reproductively mature adults through perturbation of multiple mitochondrial pathways but that induction of mitochondrial stress is not always sufficient to maintain organismal stress resistance with age.

Consistent with their ability to enhance stress resistance, RNAi against subunits of complexes I, III, and IV as well as *tomm-22* and *mrps-5* also enhanced the expression of all three HSR genes to a similar extent as *F29C4.2* (RNAi), while RNAi against *drj-21*, *tin-44*, *mrpl-1*, *mrpl-2*, and *spg-7* had only modest effects on the expression of *hsp-70(C12C8.1)*, *hsp-70(F44E5.4)*, or *hsp-16.11* following HS (Figures 2A and 2B).

To extend beyond RNAi-based experiments, we examined activation of the HSR and stress resistance at day 2 of adulthood in animals with loss-of-function mutations in mitochondrial genes (Baruah et al., 2014; Feng et al., 2001; Lakowski and Hekimi, 1996; Walter et al., 2011; Butler et al., 2010). Long-lived *isp-1(qm150)*, *nuo-6(qm200)*, *isp-1(qm150);ctb-1(qm189)*, and *clk-1(qm30)* mutants, but not short-lived *mev-1(kn1)*, *gas-1(fc21)*, and *ucr-2.3(pk732)* mutants, all exhibited a greater than 3-fold increase in median survival, a 2- to 4-fold increase in the levels of *hsp-70*, *F44E5.4*, and *hsp-16.11* mRNA, and a 2- to 3-fold increase in levels of HSP-16 protein compared to wild-type worms following HS on day 2 of adulthood (Figures 2C–2F and S2D). This was not simply due to developmental delay in the onset of reproductive maturity or reduced fecundity, as *gas-1* and *ucr-2.3* mutants both exhibited an increased time to gravid adulthood (in the case of *ucr-2.3(pk732)* mutants, this was due to a delay in embryo formation once animals reached the first day of adulthood) and reduced brood size relative to N2 (Figures S2E and S2F).

In addition to genetic perturbation, mitochondrial stress is also induced by chemicals and some microbes (Liu et al., 2014). Therefore, we hypothesized that the mitochondria-mediated maintenance of stress resistance in adulthood could constitute a physiologically relevant adaptive response to conditions that compromise mitochondrial activity. To test this, we examined stress resistance in reproductively active adults exposed to complex I (rotenone) or complex III (antimycin) inhibitors during development. We found that growth on solid media containing 2.5 μM rotenone or 2.5 μM antimycin exclusively during development activated the UPR<sup>mt</sup> without causing a pronounced developmental delay (Figure S2G) and increased stress resistance ~2-fold compared to vehicle-treated controls (Figure 2G).

Similarly, exposure to different microbes isolated from the natural environment of *C. elegans* has also been shown to activate the UPR<sup>mt</sup> (Liu et al., 2014; Samuel et al., 2016). Using three bacterial strains proposed to inhabit the natural *C. elegans* microbiome (Dirksen et al., 2016), we found that growth on the *microbacterium* MYb45 robustly activated the UPR<sup>mt</sup> (Figure S2G), whereas growth on the *achromobacter* strain MYb9 (increased brood size) or the *stenotrophomonas* strain MYb57 (no effect on brood size) did not activate the UPR<sup>mt</sup> (Figure S2G). Consistent with the ability to induce mitochondrial stress, growth on MYb45, but not MYb9 or MYb57, enhanced stress resistance nearly 3-fold compared to animals grown on the standard laboratory *Escherichia coli* strain OP50 (Figure 2H).

Together, our data suggest that physiologically relevant conditions that cause mitochondrial stress can prevent the programmed loss of stress resistance that normally accompanies the commitment to reproductive maturity in early adulthood.

**Physiological Defects Associated with Mitochondrial Perturbation Can Be Uncoupled from Beneficial Effects on the HSR and Stress Resistance**

Although no developmental delay was observed, mitochondrial perturbation through *F29C4.2* (RNAi) did result in smaller animals, reduced brood size, and increased lethargy (Figures S3A and S3B). Previous studies have shown that dilution of ETC RNAi can significantly extend lifespan without many of the physiological defects observed upon full knockdown (Rea et al., 2007). Therefore, we adopted this approach with *F29C4.2* (RNAi) to determine whether the beneficial effects on stress resistance and the HSR could be separated from the deleterious consequences of ETC knockdown.

The level of *F29C4.2* knockdown was tuned by exposing animals to undiluted *F29C4.2* (RNAi) or to *F29C4.2* (RNAi) diluted between 2- and 1,000-fold with L4440 control bacteria (Figures S3A, S3C, and S3D). Knockdown of *F29C4.2* mRNA levels and activation of the UPR<sup>mt</sup> were dose dependent (Figure S3D), and the severity of changes in body size, motility, and brood size were negatively correlated with levels of *F29C4.2* knockdown (Figure S3A). We found that a 5-fold dilution (B) Expression of *hsp-70(C12C8.1)*, *hsp-70(F44E5.4)*, and *hsp-16.11* relative to the housekeeping genes *rpb-2* and *cdc-42* on day 2 of adulthood following HS (33°C for 30 min) in worms grown on L4440 or RNAi against mitochondria-associated genes.

(C) Survival following HS (35°C, 4 hr) on day 2 of adulthood in wild-type (N2) or mitochondrial mutant strains.

(D) Expression of *hsp-70(C12C8.1)*, *hsp-70(F44E5.4)*, and *hsp-16.11* relative to the housekeeping genes *rpb-2* and *cdc-42* on day 2 of adulthood following HS (33°C, 30 min) in wild-type and mitochondrial mutant animals.

(E) Western blots of HSP-6, HSP-16, and tubulin in wild-type and mitochondrial mutant animals 24 hr post-exposure to control or HS (33°C, 30 min) conditions on day 2 of adulthood.

(F) Levels of HSP-16 relative to tubulin on day 2 of adulthood in wild-type and mitochondrial mutant animals 24 hr post-exposure to control or HS (33°C, 30 min) conditions on day 2 of adulthood. Values plotted are the mean of 3 biological replicates.

(G) Survival following HS (35°C, 4 hr) on day 2 of adulthood in wild-type animals exposed to vehicle control (1% DMSO), 2.5 μM rotenone, or 2.5 μM antimycin until the late L4 stage.

(H) Survival following HS (35°C, 4 hr) on day 2 of adulthood in wild-type animals grown on OP50 *E. coli*, MYb9 *achromobacter*, MYb45 *microbacterium*, or MYb57 *stenotrophomonas*.

Unless stated, values plotted are the mean of 4 biological replicates, and error bars denote SEM. Statistical significance was calculated relative to L4440 by two-way ANOVA with Bonferroni correction (A and B), relative to N2 by two-way ANOVA with Bonferroni correction (C), one-way ANOVA with Tukey post-analysis pairwise comparison of groups (D and F), or two-way ANOVA with Bonferroni correction compared to 1% DMSO or OP50 control groups (G and H): *p* < 0.05; **p < 0.01; ***p < 0.001.

Cell Reports 21, 1481–1494, November 7, 2017 1485
of F29C4.2(RNAi) (hereafter referred to as F29C4.2(0.2)(RNAi)) maintained stress resistance to the same level as undiluted F29C4.2(RNAi) without significant reductions in motility or brood size and with only a modest (20%) reduction in body size (although the period of egg-laying was slightly extended) (Figures S3A–S3E). F29C4.2(0.2)(RNAi) resulted in a 50%–60% reduction in F29C4.2 mRNA levels and a 30% reduction in the oxygen consumption rate (OCR) on day 2 of adulthood compared to 80% and 50% reductions, respectively, in undiluted F29C4.2(RNAi) animals (Figures 3A and 3B). The OCR increased 2-fold between day 1 and day 2 of adulthood in all treatment groups, likely due to growth and increased oocyte mass during this time period (Figure 3B). Similarly, ATP levels also increased 3- to 5-fold in L4440 and F29C4.2(0.2)(RNAi) animals during this time period but did not increase significantly in F29C4.2(0.2)(RNAi) worms (Figure 3C). ATP levels were not altered compared to L4440 in F29C4.2(RNAi) or F29C4.2(0.2)(RNAi) animals on day 1 of adulthood. However, by day 2 of adulthood, ATP levels decreased by 80% and 30% in F29C4.2(RNAi) and F29C4.2(0.2)(RNAi) animals, respectively (Figure 3C). Crucially, despite milder effects on animal physiology, OCR, and ATP levels, F29C4.2(0.2)(RNAi) still resulted in increased expression of hsp-6 and hsp-60 (Figure S3F) and maintained stress resistance through day 15 of adulthood (Figure 3D).

Reactive oxygen species (ROS) generated by mitochondrial stress have been proposed to act as life-lengthening signaling molecules (Yang and Hekimi, 2010). Levels of general ROS, H2O2, and protein carbonylation were significantly increased through day 15 of adulthood (Figure 3D). ROS and oxidative stress response at day 2 of adulthood, the induction of HSR genes and HSP-16 protein levels were increased by 2- to 3-fold following HS on day 2 of adulthood (Figures 3E and 3J). Repression of the HSR in reproductively active adults has been shown to be due to a reduced ability of HSF-1 to bind to target promoters and enhance transcription in response to HS (Labbadia and Morimoto, 2015a). Therefore we asked whether F29C4.2(0.2)(RNAi) could enhance the levels of HSF-1 and RNA polymerase II (Pol II) at HSR promoters using animals expressing a single copy of HSF-1::GFP (Li et al., 2016). HSF-1::GFP animals exhibit an enhanced HSR and stress resistance in response to F29C4.2(0.2)(RNAi) (Figures S3J and S3K). Furthermore, HSF-1 and RNA Pol II levels were increased ~2-fold at HSR promoters in F29C4.2(0.2)(RNAi) animals following HS at day 2 of adulthood (Figure 3H), without significant changes in the expression, stability, or nuclear localization of HSF-1 (Figures 3I, S3L, and S3M).

Our data demonstrate that mitochondrial stress can be “tuned” to enhance the HSR and prevent the age-related decline in stress resistance without the burden of severe physiological defects. This suggests that the influence of mitochondria on age-related changes in non-mitochondrial stress resistance pathways represents a physiologically relevant strategy by which cells and organisms use environmental cues to coordinate the onset of reproduction and the decline of stress responses with age.

**Mitochondrial Stress Prevents the Age-Dependent Collapse of Cytosolic Proteostasis**

Coincident with the rapid decline in stress resistance, proteostasis also collapses dramatically in multiple tissues during early C. elegans adulthood (Ben-Zvi et al., 2009; David et al., 2010). Therefore, we asked whether mild mitochondrial perturbation could prevent proteostasis collapse in the cytosol with age using animals expressing endogenous metastable proteins or exogenous aggregation prone proteins in intestinal cells or body wall muscle cells.

Animals expressing 44 polyglutamine (polyQ) residues fused to YFP (polyQ(44)::YFP) in intestinal cells (Mohri-Shiomi and Garsin, 2008; Prahlad and Morimoto, 2011) show diffuse polyQ::YFP fluorescence throughout the intestine on day 1 of adulthood, the intensity and localization of which is unaltered by F29C4.2(0.2)(RNAi) (Figure S4C). However, by day 7 of adulthood, greater than 80% of the population exhibits large SDS insoluble polyQ aggregates in the proximal intestinal cells (Figures 4A–4C and S4C). Growth on F29C4.2(0.2)(RNAi) profoundly reduced the number of animals containing polyQ aggregates with age and almost completely suppressed the formation of SDS-insoluble polyQ aggregates in intestinal cells (Figures 4B and 4C) without affecting expression of the O44::YFP transgene (Figure S4A). Although variable across samples, F29C4.2(0.2)(RNAi)-treated animals exhibited a trend toward increased levels of soluble polyQ protein on day 3 of adulthood, possibly due to impairments in protein turnover (Segref et al., 2014; Livnat-Levanon et al., 2014). However, this did not affect the ability to suppress aggregate formation with age (Figures 4B and S4D).
Figure 3. The Gross Physiological Defects Associated with Mitochondrial Perturbation Can Be Uncoupled from Enhanced Stress Resistance

(A) F29C4.2 mRNA levels normalized to the housekeeping genes rpb-2 and cdc-42 on day 2 of adulthood.

(B) Oxygen consumption rates at day 1 and day 2 of adulthood. Values plotted are the mean of 3 biological replicates.

(C) ATP levels at day 1 and day 2 of adulthood.

(D) Survival 48 hr following HS (35°C/14°C, 4 hr) on day 2 of adulthood.

(E–G) Expression of canonical (E) HSR (C12C8.1, F44E5.4, hsp-16.11) or (F) UPR ER (hsp-4), UPR mt (hsp-6), and oxidative stress response (gst-4) genes on day 1 and day 2 of adulthood following exposure to either control or HS (33°C, 30 min) conditions or (G) HS conditions alone. Expression of all genes was normalized to the housekeeping genes rpb-2 and cdc-42.

(H) RNA polymerase II (AMA-1) (top) and HSF-1::GFP ChIP (bottom) followed by qPCR for hsp-70, hsp-16.11, F44E5.4, and cdc-42 promoters in day 2 adults exposed to control or HS (33°C, 30 min) conditions.

(I) Western blots of HSF-1::GFP and tubulin in worms exposed to control or HS (33°C, 30 min) conditions on day 2 of adulthood. The slight shift in HSF-1 SDS-PAGE mobility corresponds to the well-documented hyperphosphorylation of HSF-1 following HS.

(J) Western blots of HSP-16, HSP-6, and tubulin at day 2 of adulthood 24 hr following exposure to control conditions or HS (33°C, 30 min) at day 2 of adulthood.

Levels of HSP-16 relative to tubulin were calculated from 3 biological replicates.

Unless stated, all values plotted are the mean of 4 biological replicates, and error bars denote SEM. Statistical significance was calculated by two-way ANOVA with Bonferroni correction followed by pairwise analysis of groups (H) or two-tailed Student’s t test (J). *p < 0.05; **p < 0.01; ***p < 0.001.
Furthermore, F29C4.2(0.2)(RNAi) also suppressed polyQ(35)::YFP aggregation and toxicity in body wall muscle cells by 20% at day 3 and day 4 of adulthood without affecting expression of the Q35::YFP transgene (Figures 4D, 4E, and S4B), and it delayed the onset of paralysis at permissive temperatures in animals harboring destabilizing point mutations in the essential muscle proteins paramyosin (unc-15ts) or myosin (unc-54ts) (Figures 4F and 4G), suggesting that mitochondrial activity is a general determinant of the timing and severity of proteostasis collapse with age in different tissues.
Finally, consistent with their ability to increase stress resistance, exposure to rotenone, antimycin, or the microbacterium *MYb45* reduced polyQ aggregation by 40%–50% at days 3–5 of adulthood (Figures 4H, 4I, and S4E) compared to control-treated animals. Although these effects were less profound than those observed with *F29C4.2(0.2)(RNAi)*, our data nonetheless suggest that mild mitochondrial stress from physiologically relevant xenobiotics and microbes can reset cytosolic proteostasis collapse with age.

**Mitochondrial Perturbation Enhances Stress Resistance and Maintains Proteostasis in an HSF-1-Dependent Manner**

Mitochondrial perturbation is primarily associated with activation of the UPR<sup>mt</sup> and restoration of mitochondrial proteostasis. An important distinction shown here is that mitochondrial perturbation also maintains the HSR and cytosolic proteostasis with age. Given that the transcription factor HSF-1 is central to the HSR, stress resistance, and cytosolic proteostasis (Akerfelt et al., 2010; Li, Labbadia and Morimoto, 2017), we asked whether the beneficial effects of mitochondrial stress require HSF-1. Therefore, we examined survival following HS in animals exposed to L4440 or *F29C4.2(0.2)(RNAi)* in combination with *hsf-1(RNAi)* or *atfs-1(RNAi)*, and in *hsf-1(sy441)* and *atfs-1(tm4525)* mutants that have a diminished HSR and UPR<sup>mt</sup>, respectively (Bennett et al., 2014; Li et al., 2016; Nagarund et al., 2015). Both RNAi-mediated knockdown and loss-of-function mutations in *hsf-1* and *atfs-1* severely dampened the ability of *F29C4.2(0.2)(RNAi)* to induce stress response genes and fluorescent reporters associated with the HSR and UPR<sup>mt</sup>, thereby demonstrating that HSF-1 and ATFS-1 are essential for *F29C4.2(0.2)(RNAi)* to enhance the HSR and UPR<sup>mt</sup>, respectively (Figures S5A–S5D).

Furthermore, while *F29C4.2(0.2)(RNAi)* significantly increased median survival following HS from 1.5 days to 4.1 days (Figure 5A), knockdown in the presence of either *atfs-1(RNAi)* or *hsf-1(RNAi)* reduced stress resistance by 25%, and 70%, respectively (Figure 5A). Similarly, *F29C4.2(0.2)(RNAi)*-mediated stress resistance was also decreased by 32% in *atfs-1(tm4525)* mutants and by 69% in *hsf-1(sy441)* mutants (Figure 5B), without affecting the efficacy of *F29C4.2(0.2)(RNAi)* to induce stress response genes and fluorescent reporters associated with the oxidative stress response through RNAi or a loss-of-function mutation of the transcription factor SKN-1 (*skn-1(zu67)* had only modest effects on stress resistance in *F29C4.2(0.2)(RNAi)* animals (Figures 5C and 5D). Our data therefore suggest that *atfs-1* and *skn-1* contribute only modestly to stress resistance in *F29C4.2(0.2)(RNAi)*-treated animals and that mild ETC perturbation promotes stress resistance predominantly through *hsf-1* and the HSR.
Consistent with our RNAi experiments, the enhanced stress resistance conferred by MYb45 or xenobiotics was also almost completely abolished in hsf-1(sy441) mutants, suggesting that animals prolong stress resistance in an HSF-1-dependent manner upon encountering mitochondrial-stress-inducing agents (Figures 5E and 5F).

Finally, we examined the relative roles of HSF-1 and ATFS-1 in the ability of mitochondrial perturbation to maintain cytosolic proteostasis with age. Strikingly, we found that atfs-1(RNAi) and skn-1(RNAi) essentially had no effect on the age-dependent aggregation of intestinal polyQ in the presence of L4440 or F29C4.2(0.2)(RNAi) (Figures 5G, 5H, and S5F). In contrast, hsf-1(RNAi) accelerated polyQ aggregation in L4440 animals and suppressed the maintenance of proteostasis in F29C4.2(0.2)(RNAi) animals by more than 5-fold (Figures 5G and S5F), suggesting that HSF-1 is integral to the ability of reduced ETC function to maintain cytosolic proteostasis and stress resistance.

Mild Mitochondrial Perturbation Increases Longevity and Extends Healthspan in an HSF-1-Dependent Manner
HSF-1 activity is tightly coupled to lifespan, with reduced HSF-1 levels reported to significantly shorten lifespan in wild-type, daf-2, age-1, and isp-1;ctb-1 animals (Hsu et al., 2003; Morley and Morimoto, 2004; Walter et al., 2011). However, hsf-1 has also been shown to be dispensable for lifespan extension conferred by pararquat-induced superoxide and in isp-1 mutants grown in the presence of fluorodeoxyuridine (FUdR) (Hsu et al., 2003; Yang and Hekimi, 2010).

Given that HSF-1 is crucial for F29C4.2(0.2)(RNAi) to maintain proteostasis and stress resistance, we asked whether the ability of mild mitochondrial perturbation to override the repression of the HSR could also improve lifespan and healthspan in an HSF-1-dependent manner. Mild mitochondrial perturbation through F29C4.2(0.2)(RNAi) increased both median and maximal lifespan by 50% (Figure 6A). However, increased lifespan through F29C4.2(0.2)(RNAi) was not dependent on atfs-1 (Figure 6A). In addition, F29C4.2(0.2)(RNAi) also maintained two well-established markers of healthspan, motility and pharyngeal pumping rate, at a more youthful state into adulthood (Figures 6B and 6C). In contrast, hsf-1(RNAi) reduced lifespan and prematurely impaired pharyngeal pumping and paralysis (Figures 6A–6C). Consistent with the dependence on HSF-1 for the maintenance of proteostasis and stress resistance upon ETC perturbation, hsf-1(RNAi) significantly truncated lifespan and healthspan to near wild-type levels in F29C4.2(0.2)(RNAi) animals (Figures 6A–6C).

Together, our data suggest that signaling through mitochondria can prevent the organismal repression of the HSR in early adulthood in order to preserve proteostasis and maintain somatic health under suboptimal environmental conditions. This has profound effects on lifespan and healthspan and suggests that mitochondria are central regulators of the timing and severity of proteostasis collapse with age.

DISCUSSION
The failure of proteostasis is a central feature of many age-related degenerative disorders, yet little is known regarding the factors that predispose cells to proteostasis collapse with age (Labbadia and Morimoto, 2015b). Here, we report that mitochondrial activity is a key determinant of the long-term activity of the HSR, proteostasis, and healthspan in adulthood and that low levels of mitochondrial stress are sufficient to maintain stress
resistance and cytosolic proteostasis with age in an hsf-1-dependent manner.

Reduced mitochondrial activity is associated with increased lifespan in C. elegans but typically comes at the cost of reduced fecundity and compromised healthspan (Bansal et al., 2015; Rea et al., 2007; Wang and Hekimi, 2015), suggesting that increased lifespan through ETC perturbation comes at the expense of a poorer quality of life and compromised fitness. Furthermore, genetic interventions that prevent the age-related collapse of proteostasis are associated with reduced brood size or sterility (Shemesh et al., 2013; Labbadia and Morimoto, 2015a), suggesting that the maintenance of proteostasis in adulthood comes at a cost to reproductive capacity. Our studies have revealed that HSF-1 activity, stress resistance, cytosolic proteostasis, and healthspan can all be maintained with age, without causing reduced brood size, through exposure to mild mitochondrial stress.

Our proposal of a relationship between mitochondria and the integrity of the cytosolic proteome is not without precedent, as recent work has demonstrated a complex interplay between mitochondrial function and cytosolic proteostasis in yeast and C. elegans (Baker et al., 2012; Kim et al., 2016; Livnat-Levanon et al., 2014; Rainbolt et al., 2013; Ruan et al., 2017; Segref et al., 2014; Wang and Chen, 2015; Wrobel et al., 2015). Given that the vast majority of mitochondrial proteins are nuclear encoded and synthesized in the cytosol, it seems logical for cells to coordinate mitochondrial status with HSF-1 activity and cytosolic proteostasis. However, it had widely been accepted that changes in mitochondrial function do not alter HSF-1 activity, primarily because previous experiments were carried out early in life and/or solely in the context of mitochondrial stress (Yoneda et al., 2004; Kim et al., 2016). Our work challenges this view and suggests that contrary to previous reports, relatively mild ETC disruption does influence the activity of HSF-1 by overriding the programmed repression of the HSR in early adulthood. Crucially, we show that this can provide long-term protection against proteotoxicity arising from the appearance of endogenous metastable proteins or from the presence of chronically expressed disease associated polyQ proteins, suggesting that this pathway allows cells to mount a more effective response to any subsequent cytosolic protein misfolding that might occur as a consequence of age or environmental insults. Furthermore, our work suggests that changes in cytosolic proteostasis arise as a short-term survival adaptation to profound defects in mitochondrial protein import (Wrobel et al., 2015; Wang and Chen, 2015) but can also be triggered by subtle stresses or environmental cues to provide long-term organisinal benefits.

Recently, changes in lipid biogenesis as a consequence of hsp-6 (mitochondrial HSP70) knockdown were shown to constitutively activate a mitochondrial/cytosolic stress response (McSR) through increased activity of ATFS-1 and HSF-1 (Kim et al., 2016). Our findings are distinct from these observations, as activation of the McSR does not occur from ETC perturbation and results in the constitutive induction of a subset of HSR genes when mitochondria are under severe duress (Kim et al., 2016). Our work suggests that a more nuanced relationship between mitochondrial stress and cytosolic protein quality control exists and that this has a direct impact on the initiation of proteostasis collapse and aging. Furthermore, our work implies that the sensing of protein folding stress can be transmitted across compartments in order to protect against subsequent stresses with age. As such, it will be crucial to understand to what extent, if at all, regulation of the age-related repression of the HSR is reliant on previously described modifiers of mitochondrial retrograde signaling.

An important question that arises from our work is whether maintenance of the HSR through mitochondrial stress is a physiologically relevant phenomenon. Our studies rule out the idea that maintenance of the HSR by mitochondrial perturbation is relevant only under circumstances where organismal health is challenged or crippled by extreme environmental adversity, as stress resistance, proteostasis, and healthspan can be maintained with minimal physiological disruption. Mitochondrial perturbation occurs naturally through imbalances in mitochondrial DNA, exposure to chemicals, and infection by bacterial pathogens (Gitschlag et al., 2016; Lin et al., 2016; Liu et al., 2014; Moullan et al., 2015; Pellegrino et al., 2014). We find that early life exposure to chemicals or microbes that can protract the reproductive period and lead to developmental delay in high does leads to the maintenance of stress resistance and cytosolic proteostasis in adulthood. This suggests that the ability to sense and adapt to potential threats to fitness before committing to reproduction could allow animals to delay egg-laying until more favorable conditions are found. Therefore, we propose that mitochondria can serve as “sentinels” to gauge fluctuations in the surrounding environment in order to influence the organismal “choice” to commit to programs that initiate reproduction at the cost of the soma, thereby preventing the repression of the HSR until animals find more favorable conditions in which to produce.

In summary, our findings provide links among mitochondrial function, regulation of the HSR, and proteostasis that may have important implications in our understanding of how different pathways converge to regulate rates of aging and fecundity. We propose that a greater understanding of the regulatory link between HSF-1 and mitochondrial function will be crucial as we attempt to uncover the drivers of proteostasis collapse in order to promote healthy aging.

EXPERIMENTAL PROCEDURES

Worm Maintenance and Strains

Worms were maintained using standard techniques as previously described (Brenner, 1974). All experiments were conducted at 20°C unless stated otherwise. Strains used in this study were wild-type (N2), Bristol, MQ887 [isp-1(qm150) IV, MO1333 nuo-6(qm200) I, MO130 clk-1(qm30) III, MO989 isp-6(qm150) IV(ctb-1(qm89), TK22 mev-1(n131), CW152 gas-1(fc21) X, NL1832 ucr-2.3(pik732) III, AM722 rls288[C1228,1fps-70[p::mCherry::myo-2p::CFP], SJ4100 zcs13[hsp-6::GFP] V, EU1 skn-1(a267) III/IV(n171)unc-7(n754) let-268 IV(V), SJ4005 zcs14[hsp-4 unpopular::GFP] V, CL2166 dvt18[gsf-4::GFP::NLS] III, AM738 rls297[kaa-4::GFP::YFP; rol-6(sa1008)], AM140 rls132[unc-540::GFP] V, CB1301 unc-54(e1301ts) I, CB1402 unc-15(e1402ts) I, AM1061 unc-119(ed9)III, rls106[hsf-1(p1)::hsp-10(nmigen):;gfp::3UTR[hsf-1] + Cbrunc-119+] II; hsf-1(ok6900) I, PSS3551 hsf-1(sy441) I, and TM4525 atts-1(tm4525)] V.

RNAi and Creation of Dilutions

RNAi was essentially performed as previously described (Kamath and Abinger, 2003), with some modifications. Nematode growth media (NGM) plates...
containing 100 µg/mL ampicillin and 1 mM isoosporyl-β-D-thiogalactoside (IPTG; Sigma) were seeded with RNAi cultures. RNAi bacteria was grown in LB containing 100 µg/mL ampicillin at 37°C for 14 hr and then induced with 5 mM IPTG for a further 3 hr at 37°C with continuous shaking. RNAi dilutions were created by thoroughly mixing RNAi cultures at an optical density 600 (OD600) of 1.5–1.6 with L4440 bacterial cultures at the same OD600. All RNAi clones used in this study were confirmed by sequencing.

Chemical Treatment of Worms and Growth on Alternate Microbes
Antimycin A (sigma) or rotenone (sigma) was dissolved in DMSO and added to NGM plates to the desired concentration before pouring. Plates containing 1% DMSO (v/v) were used as controls. Plates were seeded with OP50 E. coli and allowed to dry thoroughly before use. Worms were synchronized to xenobiotic plates by egg-laying and allowed to develop until the late L4 stage before being transferred to control plates for HS at day 2 of adulthood. Chemical containing NGM plates were stored at 4°C until use and always used within 2 weeks of pouring. For culturing worms on Microbacterium MYb45, achromobacter MYb9, and stenotrophomonas MYb57, all bacterial lines were grown and seeded onto standard NGM plates and then allowed to dry for 3 days at room temperature. All microbial plates were used within 1 week of seeding.

RNA Extraction and Real-Time qPCR
RNA extraction and real-time qPCR were performed as previously described (Labbadia and Morimoto, 2015a). Briefly, worms were lysed in 250 µL TriZol (Invitrogen), vigorously shaken with chloroform, and allowed to stand for 3 min at room temperature, and then centrifuged at 16,000 x g at 4°C. The aqueous phase was then collected, and RNA was purified using QiAGEN RNeasy min-elu columns and genomic DNA (gDNA) eliminator columns as per the manufacturer’s instructions. cDNA was synthesized from 500 ng RNA using an iScript cDNA synthesis kit (Bio-Rad). Real-time qPCR reactions were performed in triplicate for each gene using iQ SYBR green super mix (Bio-Rad) using a Bio-Rad Cycler IQ real-time PCR detection system. Relative expression of genes was determined using the relative standard curve method. All primers used can be found in Table S1.

Thermorecovery Assays
Thermorecovery assays were performed as previously described (Labbadia and Morimoto, 2015a), with the exception that lethal HS was measured as relative motility or survival following the lethal heat shock (33°C, 4 hr) or a lethal HS (35°C, 4 hr), respectively. For non-lethal thermorecovery, 25–30 animals were picked onto new seeded plates, wrapped tightly with parafilm, and submerged in a water bath at 33°C for 6 hr. Following HS treatment, worms were allowed to recover for 48 hr at 20°C, after which the proportion of the population moving normally in response to 3 plate taps was scored. Animals were scored as having abnormal movement if they exhibited paralysis, uncoordinated sinusoidal movement, sluggishness/lethargy (moving less than 1 body length per second), or irresponsiveness to plate tap. Lethal HS was conducted in the same manner but in a water bath at 35°C for 4 hr. Survival was then scored at 24-hr intervals following HS until the entire population was dead. Worms were scored as dead in the complete absence of touch response and pharyngeal pumping.

Fecundity Assays
Worms were singled onto 3-cm plates seeded with bacteria on the first day of adulthood and allowed to lay eggs. Worms were then transferred to new plates every day throughout adulthood until egg-laying had ceased, and plates containing eggs were incubated at 20°C for 48 hr, after which the number of progeny produced on each day of adulthood was counted. The mean number of progeny produced on each day of adulthood was calculated from 20 worms per treatment group.

Motility Assays
Assessment of animal motility with age was conducted as previously described (Nussbaum-Kramer et al., 2015). Briefly, 30–40 age-synchronized worms were picked onto NGM plates with a thin bacterial lawn and allowed to acclimate for 30 min. Worms were transferred to new plates to remove progeny. Plates were tapped 3 times to stimulate movement and motility was then recorded for 30 s. Motility videos were captured using a Leica stereomicroscope at 10× magnification with a Hamamatsu Orca-R2 digital camera C10600-10B and Hamamatsu Simple PCI imaging software.

Pharyngeal Pumping Assays
To score pumping rates with age, worms were transferred individually to new plates, and pharyngeal pumping was counted for 6 independent periods of 10 s to obtain the number of contractions per minute. Pumping was scored for 20 worms per group, and the average number of contractions per minute was then calculated for each population of worms.

Lifespan Assays
Worms were allowed to reach adulthood and then scored for dead worms every other day throughout life. Animals were transferred to new plates every day for the first 7 days of adulthood and then transferred to new plates every 4 days thereafter. Worms were scored as dead at the onset of pharyngeal pumping and response to touch with a platinum pick.

Fluorescence Microscopy
Worms were imaged by mounting on 5% agarose pads in 3 mM levamisole. Fluorescence and bright-field images of reporter worms were acquired using a Zeiss Axiosvert 200 microscope, a Hamamatsu Orca 100 cooled CCD camera, and Zeiss Axiovision software. Images of intestinal and body wall muscle polyQ aggregates were captured using a Leica SP8 II laser scanning confocal microscope equipped with HyD detectors. Acquisition parameters were kept identical across samples.

Statistical Analyses
Statistical significance was calculated using the log-rank (Mantel–Cox) test for lifespan assays. Either one-way ANOVA with Tukey post analysis pairwise comparison of groups, two-way ANOVA with Bonferroni post-analysis correction, or two-tailed Student’s t test were used for all other comparisons as stated in figure legends. The statistical tests used are declared in all figure legends and were calculated using GraphPad Prism (ANOVA and log-rank) or Microsoft Excel (Student’s t test).

SUPPLEMENTAL INFORMATION
Supplemental Information includes Supplemental Experimental Procedures, five figures, and two tables and can be found with this article online at https://doi.org/10.1016/j.celrep.2017.10.038.

AUTHOR CONTRIBUTIONS
J.L. designed and performed experiments, analyzed data, and constructed figures. R.I.M. designed experiments and analyzed data. J.L., R.M.B., and M.F.N. performed genome-wide RNAi screening. Y.-F.L. and C.M.H. were involved in the design of experiments and performed oxygen consumption experiments. J.L. and R.I.M. wrote the manuscript with input from Y.-F.L., C.M.H., R.M.B., and M.F.N.

ACKNOWLEDGMENTS
We thank Ilya Ruvinsky, Yoko Shibata, and Jian Li for critical reading of the manuscript and the Keck Biophysics, High Throughput Analysis, and Biological Imaging Facilities at Northwestern University for equipment use. The anti-HSP-16 antibody was a kind gift from Gordon Lithgow, and the anti-HSP-6 antibody was generated by Cindy Voisine. MYb bacterial strains were a kind gift from Hinchrich Schulenburg. We also thank David Gems for the use of general equipment and reagents. Many of the strains used in this study were provided by the CGC, which is funded by the NIH Office of Research Infrastructure Programs (grant P40 OD010440). Strain TM4525 was provided by the National Bioresource Project (Tokyo, Japan). This work was supported by NIH (National Institute on Aging) grant R01AG026847, the Ellison Medical Foundation, and the Daniel F. and Ada L. Rice Foundation (to R.I.M.) and grant R01AG047182 (to C.M.H.), as well as an ALS Association Milton Safenowitz postdoctoral fellowship and a BBSRC David Phillips fellowship (BB/P005535/1) to J.L.
