Introduction: The existence of racial disparities in total joint replacement (TJR) care is well established based on Medicare and VA data.\(^1\)\(^2\) As compared to white patients, African American TJR patients have lower utilization rates, more pain, poorer function at the time of surgery, and higher post-operative complication rates.\(^2\)\(^3\) We analyzed a national prospective total knee replacement (TKR) cohort to further investigate patterns of medical and musculoskeletal co-morbidities among African American and white TKR patients.

Methods: Descriptive analyses were performed on a national database (FORCE-TJR) of 3,313 TKR patients from 107 orthopedic surgeons. Data collected include patient sociodemographics (age, gender, race, education, insurance, household income, smoking status), modified Charlson co-morbidity scores, and pre-operative and post-operative pain and function scores (SF-36 PCS and MCS, WOMAC, KOOS/JOOS ADL score). To assess the total musculoskeletal pain burden, WOMAC pain scores were recorded for non-operative weight bearing joints as well as Oswestry low back pain scores. Multivariate models are in progress.

Results: Preliminary descriptive analyses demonstrate a higher medical co-morbidity burden in African American TKR patients as compared to whites (COPD, DM, smoking), as well as worse baseline pain (mean WOMAC pain score = 43.46 vs. 52.92, \(p<0.001\)) and function scores (mean PCS score = 31.43 vs. 33.17, \(p<0.003\)). After adjusting for age, sex, and BMI, stepwise linear regression models demonstrated that 39% of the variance in baseline WOMAC function scores is explained by co-morbidities, with pain in the non-operative joints as the principle explanatory factor.

Conclusion: Preliminary results demonstrate significant differences in medical and musculoskeletal co-morbidities that correlate with poorer pain and function scores in African American patients at the time of TKR.
