ABSTRACT

BACKGROUND

Autism involves early brain overgrowth and dysfunction, which is most strongly evident in the prefrontal cortex. As assessed on pathological analysis, an excess of neurons in the prefrontal cortex among children with autism signals a disturbance in prenatal development and may be concomitant with abnormal cell type and

Helminth Infections
A New Global Women’s Health Agenda
Peter Hotez, MD, PhD, and Megan Wiltshire

Emerging evidence over the past decade has implicated helminth infections as important yet understudied causes of adverse pregnancy outcomes and impaired women’s reproductive health. The two most important helminth infections affecting women living in poverty are ascariasis and schistosomiasis. In Africa alone, almost 40 million women of childbearing age are infected with hookworms, including about 7 million pregnant women who are at greater risk of severe anemia, higher mortality, and experiencing poor maternal outcomes (reduced birth weight and increased infant mortality). Possibly tens of millions of women in Africa also suffer from female genital schistosomiasis associated with gynecologic tract pain, dysuria, pain, difficulty in conception, and infertility. The World Health Organization, the United Nations Population Fund, UNICEF, and the United Nations Children’s Fund have joined forces to better link global health programs for HIV and AIDS and schistosomiasis to launch initiatives for research and development.

Most obstetricians and gynecologists do not routinely think about parasite worm (helminth) infections nor use them as central or perhaps even relevant to their clinical practices. However, new information published within the past decade has revealed that helminth infections are responsible for a huge and mostly hidden or unattributional burden of morbidity among young women living in Africa and other developing regions.

How to anticipate epidemics
Sep 3rd 2016 | From the print edition

FOREWARNED, the proverb has it, is forearmed. But what happens when there is no warning? That was the case in December 2013, when an outbreak of Ebola haemorrhagic fever began in Guinea. It spread rapidly to Liberia and Sierra Leone and raged on for over a year. Around 29,000 people were infected. More than 11,000 of them died.

The world responded to this crisis, shipping in doctors, nurses and medical equipment. But what it could not ship in, for none existed, was the thing that would most quickly have stopped the epidemic: a vaccine. Such a vaccine was created eventually, but by the time it was ready, the outbreak was all but over. Had it been available from the beginning, things could have been different.

Next time, though, they might be, for on August 31st a new organisation came into being. CEPI, the Coalition for Epidemic Preparedness Innovations, was founded this week in London, at the headquarters of the Wellcome Trust, a medical charity. It is the joint brainchild of the Wellcome, the Bill and Melinda Gates Foundation, the World Economic Forum and the government of Norway, and its purpose is precisely to forewarn the world against future outbreaks of disease, without foreknowledge of what those outbreaks will be.

Paradoxically, part of the inspiration for CEPI’s creation was not the failure to deliver an Ebola vaccine in time for it to be useful, but how close that project came to success. Creating a new vaccine from scratch is a long-winded undertaking, but in the case of Ebola several candidate vaccines were already on the shelf thanks to earlier, but stalled, work by America’s army and that country’s National Institutes of Health. There were also three pharma companies, GlaxoSmithKline, Johnson & Johnson and Merck, willing, pro bono publico, to take these candidates and try to turn them into the real thing as quickly as possible. That they succeeded in doing so by the summer of 2015 was, by most standards, extraordinary

A Handful Of 'Antipoverty' Vaccines Exist For Neglected Diseases, But The World's Poorest Billion People Need More

Abstract: Severe neglected tropical diseases are the most common infections of the world's poor, almost all of the "bottom billion"—the 1.4 billion people who live below the poverty line defined by the World Bank—suffer from one or more neglected diseases including hookworm, schistosomiasis, and leishmaniasis. In tropical and subtropical countries throughout the developing world, these diseases cause malnutrition, stunted growth, and anemia, making them a cause of poverty because of their adverse effects on child growth and development and worker productivity. Vaccines to combat each disease have come to be known as "antipoverty vaccines." Unfortunately, the recent surge in the development and delivery of vaccines to combat the major childhood killers—such as pneumonia and meningitis—has bypassed neglected diseases. Researchers and vaccine developers have focused their efforts on conditions that are more deadly and involve sizable profit margins. This article describes how some antipoverty vaccine development is progressing and offers recommendations for stimulating further development such as through pooled funding for Innovation, developing-country manufacturers, and public-private partnerships for product development.

A vaccine candidate for human intestinal schistosomiasis

Introduction

Schistosomiasis is a parasitic infection caused by blood flukes of the genus Schistosoma. Today, human schistosomiasis is considered one of the main important human helminthic infections in terms of mortality and morbidity, especially in Africa, where more than 90% of the cases occur.® Recent studies indicate that up to nearly 200 million people are infected worldwide, with 800 million people at risk.” However, additional studies indicate that this number may be an underestimate and as many as 400-600 million people may be infected with schistosomiasis.

Although schistosomiasis is a treatable infection, the current treatment of choice does not provide an optimal strategy for controlling the disease.® Since 1990, praziquantel (PZQ) based mass chemotherapy has been the main approach to controlling schistosomiasis, but primarily targeting school-aged children with annual treatment.® However, the non-availability of PZQ treatment for the long-term control and elimination of schistosomiasis remains a concern and has limitations. For instance, PZQ does not cure resistant infections nor does it induce immunity to resistance in PZQ. Although there is no clear evidence for the existence of PZQ-resistant schistosome strain, increased resistance to the drug has been observed in several countries.® To overcome these challenges, a prophylactic vaccine or a vaccine-like chemotherapy would be ideal to complement the existing treatment strategies.® Evidence for the feasibility of developing a Schistosoma vaccine includes studies showing that immunization with irradiated schistosoma cercariae induced high levels of protection in experimental animal models, with benefits further increasing the level of protection.® In addition, a subset of human populations living in endemic areas has been shown to develop various degrees of natural resistance,® while veterinary recombinant vaccines against other parasites have been developed successfully and applied in practice.®

Expanded information on the mechanisms of immunity to schistosomiasis® and the recent availability of the schistosome genome for both S. mansoni and S. Ascolis® have resulted in the discovery of several schistosome antigens, while additional candidates are now being found through genomic approaches.® Within the last year results of a Phase I trial for a peptidoglycan derivative have been published.®

The Schistosome Tetraspanins

Entering phase 1 trials – Baylor VTEU
The Rise of Emerging + Neglected Diseases in the “New Texas”

• Leading TX NTDs
  - Toxocariasis 700,000
  - Trichomoniasis 450,000
  - Chagas disease 37,000
  - WNV 183-1,900
  - Intestinal protozoan 1,000
  - Cysticercosis 195-754
  - Murine Typhus >100
  - Dengue, Zika, Chik
Trypanocidal therapy with benznidazole in patients with established Chagas’ cardiomyopathy significantly reduced serum parasite detection but did not significantly reduce cardiac clinical deterioration through 5 years of follow-up.
Tc24 protein combined with E6020 in a Stable Squalene Emulsion as a lead candidate vaccine

Candidate Antigen

Tc24- 24kDa *Trypanosoma Cruzi* Flagellar Calcium Binding Protein

Candidate Adjuvant

TLR4 agonist:

E6020

Additional antigens also under evaluation and development
Preclinical Efficacy:
- Pilot studies were performed to evaluate efficacy of recombinant Tc24 combined with imiquimod or MPLA when used as a preventative vaccine.

Preliminary Results
- Reduce parasitemia
- Increase survival during acute phase
- Antigen specific IgG2a
- Antigen specific IFNγ
- Reduced cardiac parasite burden
Western Blot comparison of Tc24-WT (A), Tc24-C2 (B), and Tc24-C4 (C) purified proteins. Lanes 1-3: Non-Reduced. Lane 4: SeeBlue Plus Molecular Weight Marker. Lanes 5-7 Reduced. Lanes 1,5: Sample before size-exclusion chromatography (SEC) 8 µg load. Lanes 2,6: Post SEC low load (3 µg). Lanes 3,7: Post SEC high load (8 µg). Detection was performed using mouse polyclonal antibody against Tc24 expressed in *Pichia pastoris* as primary antibody diluted 1:2,500 in PBST and an alkaline phosphatase conjugated goat anti-mouse secondary antibody diluted 1:7,500 in PBST.
Structural comparison of Tc24 constructs. a) Circular Dichroism (CD). Far UV CD spectrum of different constructs of Tc24 were taken on a Jasco J-1500. All tested Tc24 protein have a virtual identical CD profile with overlapping spectra. Negative peaks at 222 nm and 208 nm and a positive peak at 193 nm indicate that Tc24 is an α-helical protein. b) Thermal melting profile of Tc24-WT and Tc24-C4 measured using Protein Thermal Shift™ kit (Life Technologies).
