FETAL AND CHILDHOOD EFFECTS OF CHILDREN EXPOSED TO OPIOIDS, OPIOID MAINTENANCE THERAPY (OMT), AND METHAMPHETAMINE IN UTERO

Seth Peters, MPH\textsuperscript{1,2}
\textsuperscript{1}First Faculty of Medicine, Charles University, Prague, Czech Republic; \textsuperscript{2}Rhode Island Department of Health

The opioid use epidemic in the U.S. is a well-known growing problem. According to the U.S. Department of Health & Human Services, opioid use has increased nationally nearly 400\% over the past 18 years\textsuperscript{1}. Subsequently, Opioid Maintenance Therapy (OMT), methadone or buprenorphine, is expanding\textsuperscript{2}. Additionally, methamphetamine (MA) use and abuse is a continuing problem worldwide. Rates of MA use are high in the U.S. and overseas rates are greater\textsuperscript{3}. Opioid and MA use affects not only the user, but also friends, family, and the communities close to them\textsuperscript{4,5}. A child exposed to opioids, OMT, and MA in utero may have predispositions to numerous health conditions, which is also a significant impact. After an extensive PubMed search, research appears limited on illnesses, health conditions, and ongoing health related to fetal exposure to these substances. There is a lack of sufficient study on the effects of opioid, OMT, and MA use by expectant mothers on fetal and childhood health outcomes. An exhaustive database search and a retrospective epidemiological study may provide a better understanding of the health risk of children exposed to opioids, OMT, and MA in utero.
