Jean Y. Tang, MD, PhD
Joselyn Lindgren, MS
Maria Acosta-Raphael, BA
Melika Rezaee, BA
Anita M. Chanana, BS
Ervin H. Epstein Jr, MD

Author Affiliations: Department of Dermatology, Stanford University, Stanford, California (Ally, Tang); Children’s Hospital Oakland Research Institute, Oakland, California (Lindgren, Acosta-Raphael, Rezaee, Chanana, Epstein).

Accepted for Publication: May 19, 2015.

Corresponding Author: Ervin H. Epstein Jr, MD, Children’s Hospital Oakland Research Institute, 5700 Martin Luther King Jr Way, Oakland, CA 94609 (eepstein@choir.org).

Author Contributions: Drs Ally and Tang had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. Study concept and design: Ally, Tang, Epstein. Acquisition, analysis, or interpretation of data: All authors. Drafting of the manuscript: Ally, Tang, Lindgren, Acosta-Raphael, Rezaee. Critical revision of the manuscript for important intellectual content: Ally, Tang, Lindgren, Rezaee, Chanana, Epstein. Statistical analysis: Ally, Tang, Rezaee. Obtained funding: Lindgren, Epstein. Administrative, technical, or material support: Ally, Lindgren, Acosta-Raphael, Rezaee, Chanana. Study supervision: Tang, Lindgren, Epstein.

Conflict of Interest Disclosures: The funding of the clinical trials from which these data were abstracted was supported in large part by Genentech. Dr Epstein reported owning stock in Curis and Infinity. No other disclosures were reported.

Funding/Support: This investigator-initiated trial was supported in part by Children’s Hospital Oakland Research Institute, Genentech, Clinical and Translational Science Award UL1RR02413 from the National Institutes of Health, grant 1K23AR065736 from the National Institute of Arthritis and Musculoskeletal and Skin Diseases (Dr Tang), grant RO1CA109584 from the National Cancer Institute (Dr Epstein), Damon Runyon Cancer Research Foundation Clinical Investigator Award CI-54-11 (Dr Tang), and funding from the Swim Across America Foundation and the Michael J. Rainer Family Foundation.

Role of the Funder/Sponsor: The funding sources had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data, and preparation of the manuscript. The funding source had a role in reviewing and approving the manuscript and in the decision to submit the manuscript for publication.

Additional Contributions: Shufeng Li, MS, helped with statistical analysis. We thank the enrollees and the University of California, San Francisco, Clinical and Translational Science Institute.

Prevalence and Correlates of Indoor Tanning in Nonsalon Locations Among a National Sample of Young Women

Indoor tanning is a public health threat,1 and the Surgeon General has called for its reduction in adolescents and young adults.2 Research on indoor tanning has not distinguished between tanning-only salons vs other businesses and private residences that provide tanning (ie, nonsalon tanning). For example, gyms often offer free tanning, which may lead to riskier tanning habits.3 Better understanding of nonsalon tanning could have policy, prevention, and clinical implications. Our study addresses this literature gap by examining the prevalence and correlates of nonsalon tanning in a nationally representative sample of young women, who have the highest rates of indoor tanning use.

Methods | Rutgers Institutional Review Board approved the study and all participants signed an online consent form presented prior to the study. A nationally representative sample of 823 women aged 18 to 25 years (mean age, 22.7 years; 463 [56.3%] non-Hispanic white, 118 [14.3%] non-Hispanic black, 174 [21.1%] Hispanic, and 68 [8.3%] non-Hispanic other) was recruited through GfK Knowledge Networks, a research survey firm that uses address-based sampling methods to recruit a probability-based online panel of 55 000 adults from which this sample was drawn. Participants were paid $5 for completing the survey. Measures included demographics, lifetime indoor tanning use (ever used indoor tanning), current indoor tanning frequency (past 12 months), and indoor tanning location (tanning-only salon or location other than a tanning-only salon). Participants who indicated they tanned at a nonsalon location identified the location as a gym or health club, beauty shop, private home, apartment, or other location. Participants who currently use indoor tanning completed measures of indoor tanning patterns4 (event or year-round pattern) and indicated whether they used indoor tanning to improve their mood and how difficult it would be to stop using indoor tanning (proxy measure of tanning dependence5). History of depression and anxiety were also measured. Analysis of categorical variables used χ2 difference tests and continuous outcomes used bivariate general linear models in SPSS Complex Samples, version 21 (SPSS Inc).

Results | Forty-one percent (unweighted n = 123) of participants who ever used indoor tanning and 24.6% (n = 34) of current indoor tanning users reported nonsalon tanning (Table 1). Participants who had ever used indoor tanning most commonly used indoor tanning at gyms (64 [18.9%]), beauty shops (39 [13.8%]), and private homes (40 [13.2%]). Participants who were currently using nonsalon indoor tanning most often used indoor tanning at gyms (20 [9.8%]), private homes (13 [7.7%]), and apartment complexes (10 [7.5%]). The number of lifetime indoor tanning sessions was

Results | Forty-one percent (unweighted n = 123) of participants who ever used indoor tanning and 24.6% (n = 34) of current indoor tanning users reported nonsalon tanning (Table 1). Participants who had ever used indoor tanning most commonly used indoor tanning at gyms (64 [18.9%]), beauty shops (39 [13.8%]), and private homes (40 [13.2%]). Participants who were currently using nonsalon indoor tanning most often used indoor tanning at gyms (20 [9.8%]), private homes (13 [7.7%]), and apartment complexes (10 [7.5%]). The number of lifetime indoor tanning sessions was
more than 2 times greater for those who had ever used a nonsalon location (75.7) than those who had not (35.0) ($P = .02$) (Table 2). In participants who were currently using nonsalon indoor tanning, tanning to improve mood ($P = .06$) and year-round tanning ($P < .001$) were more common relative to participants who used tanning-only salons. Participants who were currently using nonsalon indoor tanning reported a history of depression almost 3 times higher ($P = .047$) and difficulty stopping indoor tanning ($P = .01$) than those exclusively using tanning-only salons.

**Discussion**  |  Our findings indicate nonsalon indoor tanning is common with current indoor tanning users (24.6%) and those who have ever used indoor tanning (41.0%). Gyms are the most typical location of nonsalon indoor tanning. Nonsalon indoor tanning users report more depression, tanning dependence, tanning to improve mood, and lifetime tanning. They are also more likely to use indoor tanning year round. Some indoor tanning users might seek out gyms to circumvent the federal tanning excise tax, which gyms are not required to collect. Nonsalon tanning locations also seem to attract more high-risk tanners (ie, those who are depressed or have a dependence on tanning). Despite this evidence, we know little about the supervision, regulation, or maintenance of nonsalon tanning locations. Future research needs to assess tanning location along with other indoor tanning variables. Research should examine the reasons nonsalon locations are popular with high-risk tanners, as well as factors that may explain the use of nonsalon locations, such as convenience, cost, physical activity (eg, gym tanning), and living arrangements (eg, apartment tanning). Private home tanning, which has no regulations or oversight, should be carefully studied. We need to better characterize the supervision, maintenance, and regulation of nonsalon locations to inform clinical, prevention, and policy decisions.

Limitations of this study include its focus on adult women only, cross-sectional data, and the inability to assess nonsalon categories independently owing to small sample size.

Physician counseling to reduce indoor tanning is a recommended preventive health service. Physicians should assess patients’ tanning locations since nonsalon tanning may indicate more risky behavior.

OBSERVATION

Erythema in Skin Adjacent to Area of Long-term Brimonidine Treatment for Rosacea: A Novel Adverse Reaction

We describe a case of compensatory vasodilation in the vasculature surrounding the site of long-term brimonidine use for the treatment of rosacea.

Report of a Case | A 57-year-old woman with a medical history of rosacea, anxiety, hyperlipidemia, and hypertension presented with persistent, patchy erythema on the lateral face and neck of several weeks' duration. Seven months before presentation, she had been prescribed brimonidine, 0.33%, topical gel for persistent facial erythema secondary to rosacea. She reported appropriate use of the medication, applying the prescribed amount only to affected areas on her central face. Physical examination revealed marked bright erythema diffusely covering areas of the lateral cheeks, neck, and upper chest (Figure, A). Interestingly, there was clear sparing of the sites of brimonidine application on the central face.

Review of systems revealed only that the eruption was associated with mild burning. Prior to presenting to our clinic, she saw several other dermatologists. Over the course of these visits, several laboratory studies were ordered, including a complete blood cell count with differential, a complete metabolic panel, a lipid panel, and measures of C1, total complement, antinuclear antibody (ANA), and tryptase, all of which yielded normal results. A cutaneous punch biopsy of the left neck was performed and revealed nonspecific findings of photodamaged skin with telangiectasias and scant perivascular lymphocytic inflammation with
