Abstract

In rats, the respective contribution of the thyroid and peripheral tissues to the pool of $T_3$ remains unclear. Most, if not all, of the circulating $T_3$ produced by extrathyroidal sources is generated by 5'-deiodination of $T_4$, catalyzed by the selenoenzyme, type I iodothyronine 5'-deiodinase (5'D-I). 5'D-I in the liver and kidney is almost completely lost in selenium deficiency, resulting in a marked decrease in $T_3$ deiodination and an increase in circulating $T_3$ levels. Surprisingly, circulating $T_3$ levels are only marginally decreased by selenium deficiency. In this study, we used selenium deficiency and thyroidectomy to determine the relative contribution of thyroidal and extrathyroidal sources to the total body pool of $T_3$. Despite maintaining normal serum $T_3$ concentrations in thyroidectomized rats by $T_4$ replacement, serum $T_3$ concentrations remained 55% lower than those seen in intact rats. In intact rats, restricting selenium intake had no effect on circulating $T_3$ concentrations. Decreasing 5'D-I activity in the liver and kidney by > 90% by restricting selenium intake resulted in a further 20% decrease in serum $T_3$ concentrations in the thyroidectomized, $T_4$ replaced rats, suggesting that peripheral $T_4$ to $T_3$ conversion in these tissues generates approximately 20% of the circulating $T_3$ concentrations. While dietary selenium restriction markedly decreased intrathyroidal selenium content (> 95%), intrathyroidal selenium content decreased by only 27%. Further, thyroid 5'D-I activity actually increased 25% in the selenium deficient rats, suggesting the continued synthesis of this selenoenzyme over selenoproteins in other tissues in selenium deficiency. These data demonstrate that the thyroid is the major source of $T_3$ in the rat and suggest that extrathyroidal $T_4$ to $T_3$ conversion may account for most of the $T_3$ released by the thyroid. (J. Clin. Invest. 1993. 91:2709-2713.) Key words: deiodination • selenium • thyroid • hormone metabolism • $T_4$ to $T_3$ conversion

Introduction

In mammals, the relative contribution of thyroidal and extrathyroidal sources to the total body pool of the metabolically active iodothyronine, 3,5,3'-triiodothyronine ($T_3$), is unclear. $T_3$ can be derived from conversion of the prohormone thyroxine ($T_4$) by outer ring (5')-deiodination in the peripheral tissues, by $T_4$ to $T_3$ conversion within the thyroid gland, and by direct secretion of de novo synthesized thyroidal $T_3$. Estimates of the contribution of extrathyroidal $T_4$ to $T_3$ conversion to the total $T_3$ pool vary from 20% to 100% in the rat (1-3) and the thyroid accounts for the remainder of the $T_3$ produced daily. Lauher used in situ thyroid perfusion to directly examine the contribution of the thyroid to the $T_3$ pool and reported that extrathyroidal $T_4$ to $T_3$ conversion accounted for a considerable portion of the $T_3$ secreted from the dog thyroid (4, 5). Thus, both extrathyroidal and intrathyroidal $T_4$ to $T_3$ conversion appear to participate in the daily production of $T_3$.

$T_4$ to $T_3$ conversion is catalyzed by the enzyme, iodothyronine 5'-deiodinase. Two isoforms of iodothyronine 5'-deiodinase have been identified. The most abundant form, type I iodothyronine 5'-deiodinase (5'D-I), is found in liver, kidney, and thyroid (6) and contains the rare amino acid selenocysteine (7-9). Tissue content of 5'D-I in the liver and kidney is proportional to selenium intake (10). The other isoform, type II iodothyronine 5'deiodinase (5'D-II), is abundant in the brain, pituitary, and brown adipose tissue and does not contain selenium (11, 12). $T_3$ generated by 5'D-I is released into the general circulation, while the majority of the $T_3$ produced by 5'D-II remains with the cell. The ability to manipulate 5'D-I levels by altering the dietary intake of selenium provides the means to examine the contribution of 5'D-I to total $T_3$ production. Selenium deficiency leads to an almost complete loss of 5'D-I in the liver and kidney and a 40-50% increase in the serum $T_4$ concentration (10, 12-14). This increment in circulating $T_4$ is completely accounted for by the prolonged metabolic half-life of the iodothyronine due to the loss of 5'D-I (14). Paradoxically, serum $T_3$ concentrations are not reciprocally affected and decrease by no more than 20%, if at all (12-14). While serum $T_4$ concentrations are marginally depressed by selenium deficiency, circulating $T_4$ sulfate concentrations increase nearly twofold (12, 14). Serum TSH levels remain near normal despite the elevated circulating $T_4$ in the selenium-deficient animal (12-14). Thus, despite the marked decrease in hepatic and renal $T_4$ to $T_3$ conversion in the absence of selenium, other sources of $T_3$ appear to be made available in animals lacking 5'D-I.

There are several possibilities to account for the discordance between the near complete loss of 5'D-I and the marginal fall in circulating $T_3$ observed in selenium deficiency. They include (a) diminished $T_3$ clearance, (b) increased thyroid $T_3$ secretion, and/or (c) enhanced recovery of $T_3$ from sulfo-conjugates released into the gut in the enterohepatic cycle. Previous work has shown that $T_3$ clearance is only marginally decreased by selenium deficiency and that the 20-25% increase in the metabolic half-life of this iodothyronine is insuffi-
cient to maintain the steady-state levels of T₃ observed in serum (14). The contribution of the thyroid to the T₃ pool in the selenium-deficient rat remains to be determined. Likewise, the contribution of enterohepatic recycling of T₃ or its conjugates to the circulating T₃ pool is unclear.

In this study, we determined the source(s) of circulating T₃ in selenium-deficient rats. The data show that the thyroid gland serves as a major source of circulating T₃ in the rat and suggest that intrathyroidal T₄ to T₃ conversion accounts for much of the T₃ secreted by the thyroid.

Methods

Animals and reagents. Weanling male Sprague-Dawley rats (40-50 g) supplied by Charles River Laboratories (Wilmington, MA) were used in all experiments. The study was approved by the Animal Research Committee and complies with the institutional assurance certificate of the University of Massachusetts Medical Center. Rats were fed a torula yeast based semisynthetic diet (Teklad Premier Laboratory Diets, Madison, WI) for 5 wk. The selenium-deficient diet (TD 86298) contains less than 16 μg/kg selenium and the selenium-replete diet (TD 91259) is the same base diet supplemented with 200 μg/kg selenium as Na₂SeO₃. Rats were housed in stainless steel cages, and distilled water was available ad lib. Body weight (BW)¹ was monitored biweekly.

Analytical procedures and hormone assays. In all experiments, animals were killed by decapitation and exsanguinated, except where noted. Liver was homogenized in 4 vol (wt/vol) of 20 mM potassium phosphate buffer (pH 7.4), 150 mM NaCl, and in 4 vol (wt/vol) of 250 mM sucrose, 20 mM Hepes buffer (pH 7.0), 1 mM EDTA, and 1 mM DTT and stored at −20°C for determination of glutathione peroxidase activity (GPx) and 5'D-I activity, respectively. Thyroid glands were weighed and homogenized in 800 μl of 250 mM sucrose, 20 mM Hepes buffer (pH 7.0), 1 mM EDTA, and 1 mM DTT for determination of 5'D-I activity.

The degree of selenium deficiency in the rats was determined by the decrease in hepatic GPx activity. GPx activity was determined from the oxidation of NADPH in the presence of 0.35 mM l-butyl hydroperoxide monitored spectrophotometrically at 340 nm (15). Samples were run in duplicate and results were expressed as nmol NADPH oxidized/min per mg protein. Hepatic GPx activities in intact, selenium-replete and thyroidectomized, T₄ replaced, selenium-replete rats were 598±58 nmol NADPH oxidized/min per mg protein (n = 9) and 906±53 nmol NADPH oxidized/min per mg protein (n = 12), respectively.

Type I iodothyronine 5'-deiodinase activity was determined by the release of radioiodide from 10 μM [¹³¹I]T₄ in the presence of 20 mM DTT (5'D-I) (16). Samples were run in duplicate and results were expressed as units/mg protein; 1 unit of 5'D-I enzyme activity represents the release of 1 pmol radioiodine/min per mg protein at 37°C. Hepatic type I iodothyronine 5'-deiodinase activities in intact, selenium-replete and thyroidectomized, T₄ replaced, selenium-replete rats were 224±15 U/mg protein (n = 12) and 114±8 U/mg protein (n = 9), respectively.

Serum TSH was measured in duplicate by RIA using materials obtained from the National Pituitary Agency, National Institutes of Health (Bethesda, MD). Serum T₄ and T₃ concentrations were determined in duplicate by species-adapted specific RIA.s. Selenium was quantified by measuring the 162 KeV gamma ray produced during the decay of radioactive ⁷⁷Se after irradiation of the sample at a neutron flux. The sensitivity was 0.05 ppm (Research Reactor Facility, University of Missouri–Columbia, Columbia, MO) (17).

Protein was measured by the method of Bradford (18).

¹. Abbreviations used in this paper: BW, body weight; GPx, glutathione peroxidase activity.

Experimental procedures

Effect of altered selenium intake on serum T₄, T₃, and TSH concentrations in T₄ replaced, thyroidectomized rats. 35 rats (22 selenium-supplemented and 13 selenium deficient) were used in this experiment. 3 wk before being killed, 12 selenium-supplemented and 6 selenium-deficient rats were anesthetized using 7 mg ketamine and 0.6 mg xylazine/100 g BW and the thyroid glands removed. T₄ replacement was begun one day after thyroidectomy by daily intraperitoneal injections of T₄ (1.1 μg/100 g BW) for 2 wk. For the final 7 d of the experiment, serum T₄ concentrations were maintained at euthyroid levels by the use of an osmotic minipump (Alzet 2001; Alza Corp., Palo Alto, CA) calculated to deliver T₄ at a rate of 1.1 μg/100 g BW per day. T₄ (Sigma Chemical Co., St. Louis, MO) used for hormone replacement was >99.7% pure as measured by HPLC.

Effect of selenium deficiency on the selenium content and 5'D-I activity in the thyroid gland. 15 rats (8 selenium supplemented, and 7 selenium deficient) were anesthetized as described above and perfused through the aorta with 40 ml of ice-cold saline. The exsanguinated thyroid gland and liver were removed and frozen at −70°C for subsequent determination of selenium content by neutron activation analysis. In a parallel experiment, thyroid and liver 5'D-I activities were determined in 10 selenium-supplemented and 10 selenium-deficient rats.

Effects of selenium deficiency on intrathyroidal metabolism of ¹³¹I. Intrathyroidal metabolism of ¹³¹I was determined in groups of 5 rats (5 selenium supplemented and 5 selenium deficient). Animals were killed 2 h after the intraperitoneal injection of 10 μg Na¹³¹I (16.2 Ci/μg). Thyroid glands were then dissected free of connective tissue and homogenized in 500 μl of sodium barbital buffer (pH 8.6) containing 20 mM methimazole and 4 mM KI. The percent uptake of radioiodide and the distribution of the ¹³¹I between MIT, DIT, T₃, and T₄ was determined by descending paper chromatography after pronase digestion of thyroid homogenates according to Vagenakis et al. (19).

Statistics

The results are presented as mean±SE. Statistical significance (P < 0.05) was determined using the Student's t test for unpaired values.

Results

Effects of selenium status on serum T₄, T₃, and TSH concentrations in T₄ replaced, thyroidectomized rats. During the 5-wk experimental period, body weights increased from 55 to 330 g in the euthyroid rats (intact) (n = 17) and from 55 to 289 g in the thyroidectomized rats replaced with T₄ (T₄ replaced) (n = 18), indicating that hormone replacement was almost complete in the thyroidectomized animals. No differences in growth were observed between the selenium-deficient and selenium-supplemented rats. Selenium deficiency resulted in a 97% decrease in hepatic GPx activity and a parallel 93% decrease in hepatic 5'D-I activity in both the intact and T₄ replaced rats indicating that the animals were selenium deficient. As shown in Fig. 1, in selenium-supplemented rats, serum T₄ concentrations were similar in the intact and T₄ replaced groups (A). Selenium deficiency resulted in the expected increase in the serum T₄ concentrations in both the intact and T₄ replaced groups (P < 0.05, A vs. B).

Although the serum T₄ concentrations were identical in the selenium-supplemented intact and T₄ replaced rats, serum T₃ concentrations were not normalized and T₃ concentrations in the T₄ replaced rats remained 55% lower than those in the intact group (Fig. 1 C). Selenium deficiency did not significantly affect serum T₃ values in the intact rats (1.23 nM±0.14 vs. 1.11±0.10, selenium-supplemented vs. selenium-deficient...
and thyroidal 5'D-I appears to be a selenoprotein (7), the near normal serum T₃ concentrations found in intact, selenium-deficient animals raised the possibility that thyroidal 5'D-I was unaffected by selenium deficiency. Thus, we determined the effects of selenium deficiency on thyroidal selenium content (Fig. 2) and on 5'D-I activity in the thyroid (Fig. 3). Rats fed the selenium-deficient diet had a > 97% fall in selenium content in the liver and a corresponding > 93% decrease in liver 5'D-I activity. However, in the thyroid, the selenium-deficient diet resulted in only a modest 27% decrease in selenium content, and paradoxically, the 5'D-I activity was increased by 25% (P < 0.05).

Effects of selenium deficiency on intrathyroidal metabolism of ¹³¹I. To evaluate the influence of altered selenium intake on intrathyroidal iodine metabolism, we determined the effects of selenium deficiency on the thyroid gland's ability to concentrate and organify iodine. Thyroid uptake of ¹³¹I was unaffected by selenium intake, and there were no differences in the synthesis of the ¹³¹I-labeled iodotyrosines (MIT and DIT) or iodothyronines (T₄ and T₃) between selenium-deficient and selenium-supplemented rats (Table I).

Discussion

Controversy surrounds the contribution of the various tissues to T₃ production in the rat. DiStefano (1) estimated that 47% of T₃ originates from both thyroidal secretion and extrathyroidal T₄ to T₃ conversion in liver and kidney, while the remain-

Intrathyroidal metabolism of \(^{131}\text{I}\) was determined in 5 selenium-supplemented (Se+) and 5 selenium-deficient (Se-) rats as described in Experimental procedures. Results are expressed as mean±SE.

Intrathyroidal metabolism of \(^{131}\text{I}\) was determined in 5 selenium-supplemented (Se+) and 5 selenium-deficient (Se-) rats as described in Experimental procedures. Results are expressed as mean±SE.

ing 53% comes from \(T_4\) to \(T_3\) conversion in the slowly equilibrating pools, such as brain, skin, and muscle. Kinlaw et al. (3) revised their earlier estimate that only 20% of \(T_3\) is produced by extrathyroidal \(T_4\) to \(T_3\) conversion in the rat (2) and suggested that essentially all \(T_3\) is produced by \(T_3\) to \(T_4\) conversion. They also speculated that there is little or no direct secretion of \(T_3\) by the thyroid.

The current data demonstrate that at least 55% of circulating \(T_3\) comes from the thyroid gland in the intact, selenium-supplemented rat. Since liver and kidney \(5'D-I\) still contribute to the pool of circulating \(T_3\) in these rats, it is difficult to estimate the relative contribution of the thyroid to total body \(T_3\) concentrations. Moreover, the failure of \(T_4\) replacement to normalize serum \(T_3\) concentrations in thyroidectomized rats, resulting in reduced liver \(5'D-I\) activity, further complicates the analysis of the sources of circulating \(T_3\). However, in the selenium-deficient rat, liver and kidney \(5'D-I\) are virtually absent (12), and the contribution of the thyroid to the serum \(T_3\) pool can be approximated. The contribution of thyroidal \(T_3\) derived from thyroglobulin and that from thyroidal \(T_4\) to \(T_3\) conversion to the circulating \(T_3\) pool in these animals, as estimated from the data presented in Fig. 1 panel \(D\), is approximately 65% and the residual serum \(T_3\) concentrations present in these rats lacking both the thyroid and extrathyroidal \(5'D-I\) is in excellent agreement with previously measured values (12). The source of the residual \(T_3\) in the serum of thyroidectomized rats with essentially undetectable serum \(T_3\) concentrations and no hepatic and renal \(5'D-I\) remains unclear. Taken together, extrathyroidal \(T_4\) to \(T_3\) conversion contributes 20–25%, and thyroidal \(T_4\) to \(T_3\) conversion and \(T_3\) derived from thyroglobulin contributes 55–65% of the total body pool of \(T_3\). Thus, nearly all the circulating \(T_3\) derived from \(T_4\) appears to be produced by the selenoenzyme, \(5'D-I\).

Thyroidectomy resulted in a marked increase in serum TSH concentrations in both selenium-supplemented and selenium-deficient rats despite the maintenance of serum \(T_4\) concentrations identical to those observed in the respective intact groups. The presence of increased serum TSH concentrations, decreased serum \(T_3\) concentrations, and normal or elevated serum \(T_4\) concentrations indicates that circulating \(T_3\) plays an important role in regulating TSH secretion (12, 20, 21). Previously, we found a modest increase in serum TSH concentrations (12) in selenium-deficient rats that was proportional to the fall in circulating \(T_3\) suggesting that TSH levels may actu-

ally be slightly elevated for some period during dietary restriction of selenium.

Dietary restriction of selenium intake had only a marginal effect on the selenium content and levels of the selenoenzyme \(5'D-I\) in the thyroid gland. Thus, while there was a near complete loss in hepatic selenium content and \(5'D-I\) activity, the thyroid preserves its selenium stores and \(5'D-I\) activity was increased by 25% in selenium-deficient rats. This increase in intrathyroidal \(5'D-I\) may be due to TSH mediated stimulation of \(5'D-I\) activity (22, 23) resulting from small increases in circulating TSH that may occur in selenium-deficient rats. Thus, despite the loss of extrathyroidal \(T_3\) to \(T_4\) conversion, the thyroid retains the ability to catalyze the \(5'D\) deiodination of \(T_4\).

Similar preservation of thyroidal selenium stores was recently observed in rats fed a selenium-deficient diet for two generations. Behne and co-workers have observed that the thyroid gland and brain exhibited the highest avidity for selenium (24). Arthur et al. (25) recently found that thyroidal GPx activity fell by ~ 50% after 5 wk of selenium deficiency. Since the 25% increase in thyroidal \(5'D-I\) occurred during this same time period in our studies, these data suggest that the thyroid is resistant to the effects of selenium deficiency and that thyroidal \(5'D-I\) is preserved over other selenoproteins in selenium-deficient animals. The thyroid is not unique in this regard since the testis and brain also preferentially preserve selenium over other organs (26).

In this study, intrathyroidal iodine metabolism was also unaffected by selenium deficiency, whereas inconsistent results have been reported on the effects of selenium deficiency on intrathyroidal metabolism by others. Goldstein et al. observed a decrease in \(\text{PB}^{131}\text{I}\) after in vitro incubation of thyroid glands from selenium-deficient rats with \(131\text{I}\) (27). Arthur et al. (25) found a decrease in both \(T_4\) and \(T_3\) content in the thyroid gland from selenium-deficient rats, while Meinhold et al. (28) found no change in \(T_4\) and \(T_3\) content in the thyroid from rats fed a selenium-deficient diet. Taken together, these data suggest that secretion of de novo synthesized \(T_3\) is unaffected by selenium deficiency. It is generally assumed that 70–80% of the circulating \(T_3\) concentrations (29, 30) is derived from \(T_4\) to \(T_3\) conversion in human and similar, albeit, more variable estimates have been made for the rat and that the liver, kidney, and thyroid contain nearly all the \(5'D-I\) activity in the body (6, 30). Since extrathyroidal \(5'D-I\) contributes 10–25% of the \(T_3\) production (see above), then more than 50% of the \(T_3\) in the thyroid effluent is likely to be derived from intrathyroidal \(T_4\) to \(T_3\) conversion of \(T_4\) liberated from thyroglobulin.

The finding that the majority of \(T_3\) in the rat derives from the thyroid provides a potential explanation for the apparent discordance between the observed \(K_m\) for \(5'D-I\) and the concentration of \(T_4\) available to extrathyroidal tissues. In vitro estimates of the \(K_m\) for \(T_4\) for \(5'D-I\) range between 0.5 and \(1 \mu M\) (6, 30), while the \(T_4\) available to the tissues ("free hormone") is 3–4 orders of magnitude less, indicating that catalysis by \(5'D-I\) in peripheral tissues is very inefficient. However, intracellular \(T_4\) levels in the thyroid would be expected to be much greater than those in the circulation, and the \(K_m\) for \(T_4\) of \(5'D-I\) may reflect the substrate available in the thyroid rather than that in the circulation.

In conclusion, the current study demonstrates that the thyroid gland is a major source of circulating \(T_3\) in rats, accounting for approximately 55% of total \(T_3\) production. The contri-
bution of intrathyroidal $T_4$ to $T_3$ conversion to $T_3$ homeostasis appears to be important, but the exact contribution remains to be determined.
