## Abstract

Online patient portals may be effective for engaging patients with mental health conditions in their own health care. This retrospective database analysis reports patient portal use among Veterans with mental health diagnoses. Unadjusted and adjusted odds of portal feature use was calculated using logistic regressions. Having experienced military sexual trauma or having an anxiety disorder, post-traumatic stress disorder, or depression were associated with increased odds of portal use; bipolar, substance use, psychotic and adjustment disorders were associated with decreased odds. Future research should examine factors that influence portal use to understand diagnosis-level differences and improve engagement with such tools.

**Keywords** Engagement · Health information technology · Mental health · Patient portals · Veterans

Mental health concerns such as depression, anxiety, post-traumatic stress disorder (PTSD), and substance use disorders are highly prevalent among US Veterans (Trivedi et al. 2015), and have been associated with dire consequences including elevated rates of suicide and homelessness (Metraux et al. 2013; Tsai and Rosenheck 2015; Wisco

et al. 2014). While essential, engaging Veterans in mental health care is often challenging and met with a wide array of barriers. Engagement may be facilitated by the provision of accessible treatment options that are available remotely as well as in-person, in particular to address barriers around the stigma of in-person treatment (Berger et al. 2005). Electronic health resources for mental health, such as telehealth for service delivery, virtual asynchronous communication platforms, and other online tools can facilitate both initial and sustained engagement with mental health care (Fletcher et al. 2014; Kipping et al. 2016; Myers and Lieberman 2013).

Online patient portals linked or “tethered” to electronic health records (EHRs) offer access to personal health information and the ability to conduct transactions with a healthcare system. Portals are a potentially beneficial tool for improving patient engagement, healthcare experiences, and outcomes (Otte-Trojel et al. 2014). Within the context of care for physiological conditions, patient portals have been associated with positive outcomes such as improved communication, self-management of conditions, more appropriate healthcare use, increased adherence to medications, and improved satisfaction (Kruse et al. 2015; Lau et al. 2014; Sarkar et al. 2014; Wade-Vuturo et al. 2013).

Within the United States (US), the Department of Veterans Affairs (VA) healthcare system provides a comprehensive array of services to eligible US military Veterans who choose to utilize them. The VA system of care is comprised of approximately 1250 nationally-dispersed facilities (medical centers and outpatient clinics) offering inpatient, outpatient, home and community-based services to more than 9 million patients across their lifespan (US Department of Veterans Affairs [VA] 2019a, b). Eligibility for VA care is determined based on a number of criteria, first and foremost of which is US military service (VA 2018a).

The VA introduced its tethered online patient portal, My HealtheVet (VA 2018b), in 2003 and has continued to add new content and features to the system in the ensuing years. The My HealtheVet portal currently offers various features including: online prescription refills, asynchronous secure messaging with healthcare team members, viewing appointments and health record data such as lab/test results, health education resources, information about VA benefits, the ability to input and track personal health information, and the ability to access and download one’s health record, including clinical progress notes, via the ‘Blue Button’ (VA, 2018b). Of note, one of the potential benefits of the Blue Button is that Veterans who receive both VA and community-based care can use it to share their health information with non-VA healthcare provider(s) (Klein et al. 2015).

The My HealtheVet system employs a tiered access model. Visitors to the portal can access some of its features and can also self-register for a basic account to enter personal health information and access various health education resources. Those patients who create a basic account and are matched by the system through a Master Veteran Index are automatically upgraded to an advanced account which offers access to more features. VA patients who also complete a one-time identity authentication process either in-person or online are further upgraded to a premium account which offers access to all My HealtheVet portal features. Table 1 presents the features that were available through My HealtheVet during our study period (fiscal year (FY) 2013) and their associated level of access. As described below, the analysis reported in this paper focuses on a core subset

of these features intended to support interaction between Veterans and the VA healthcare system (see italicized text in Table 1). There are currently over 4.3 million registered My HealtheVet users, and over 2.6 million have been identity-authenticated (VA 2018c) and have a premium account.

Patient portals such as My HealtheVet have the potential to be highly valuable in the context of mental healthcare delivery. The health information that patients share through a portal can be useful for care delivery and coordination, and portal communication features offer an accessible way for patients to report to their providers that they are experiencing mental health concerns such as depression (Wuerdeman et al. 2005), both in terms of symptom onset or changes in symptomology or symptom severity. My HealtheVet is unique in offering patients online access to their clinical progress notes (VA Notes), including those associated with mental health treatment (Denneson et al. 2017). Early studies revealed some ambivalence among VA mental health clinicians regarding patient access to clinical notes in the context of mental health care (Dobscha et al. 2016), although studies with VA patients have suggested that thoughtfully-constructed clinical notes could be a tool to further foster patient trust (Cromer et al. 2017).

My HealtheVet and other patient portals also provide opportunities for patients to engage with their healthcare management, through features such as online appointment scheduling and viewing upcoming appointments (which may improve appointment attendance) and medication refills (which may facilitate medication adherence). Literature suggests that patients, including those with mental health concerns such as depression and anxiety, want to use the various features that many patient portals now offer (Albert et al. 2015; Delbanco et al. 2010).

Patient portals can serve as an essential resource in mental healthcare delivery by increasing patient engagement and access, and potentially reducing stigma associated with treatment seeking. However, little is known about patient portal use among individuals with mental health concerns. An earlier analysis of My HealtheVet use in 2012 showed that adoption and use of the portal varied by patient diagnosis, and that some mental health diagnoses were associated with higher rates of adoption (Shimada et al. 2014).

Since that time, many new features have been added to the My HealtheVet portal, which may have changed rates of adoption (Nazi et al. 2018). Some of these new features, such as VA Notes and the ability to view other information from the VA’s EHR, may be especially meaningful for patients with mental health diagnoses, although few studies to date have evaluated the relationship between mental health diagnosis and use of specific My HealtheVet features. For these reasons, the objective of this analysis was to examine (1) the extent to which Veterans with mental health diagnoses use VA’s My HealtheVet portal, and (2) how use of portal

features varies across Veterans with different mental health diagnoses.

## Methods

### Study Design

Data were collected as part of a larger study, which was comprised of a retrospective database analysis examining My HealtheVet use among approximately 3.5 million

Veterans receiving VA health care (see Fig. 1, cohort derivation diagram), including impacts on VA healthcare use, feature use, dual use in which Veterans also receive care in community settings, and cost. The focus of this analysis was use of My HealtheVet (in general and in terms of specific core features) among the Veterans from that overall sample with various mental health diagnoses.

**Fig. 1** Sample derivation diagram

## Participants

Starting with the overall sample for the larger study noted above (see Fig. 1), we selected Veterans with a mental health diagnosis (defined as having at least two instances of the diagnosis documented in the VA administrative records during outpatient encounters or one instance documented in the VA administrative records during an inpatient encounter) in the year prior to the index date. The index date was defined as the first use of My HealthVet in FY2013 for the My HealthVet users (with no history of use prior to FY2013) and the first day of that fiscal year (Oct. 1, 2012) for the comparison group. ICD-9 codes used to define each mental health diagnosis (except for military sexual trauma (MST)) were based on definitions detailed in Carlson et al. (2010) (see Table 2). A Veteran was classified as having experienced MST if they had a positive MST indicator noted in VA administrative records in the year prior to their index date. We then sampled 10% of all Veterans who received healthcare in the VA in FY2013 but had never used My HealthVet, and excluded Veterans

with less than two encounters before or after the index date.

Veterans who were deceased, aged younger than 18 or older than 104, and those with missing data on variables included as covariates in adjusted models (distance to nearest VA; region of residence; urbanicity of residence; enrollment; income) were excluded from the sample. The final analytic sample for this study was composed of 159,581 Veterans who use VA healthcare services with at least one mental health diagnosis.

## Measures and Data Sources

**Demographics** Information about Veteran characteristics were obtained from the Veterans Health Administration Medical SAS Databases, which contain data extracted from patient electronic medical records (VA Information Resource Center [VIREC] 2011a, b), and included gender, age, race, ethnicity, and US geographic region of residence (i.e., mid-west, northeast, south, west, other). The distance between the nearest VA facility to the Veteran and the zip code associated with the Veteran's address were used to determine the distance to their nearest VA. A Veteran's VA enrollment group, a classification system used to determine copayment for VA services based on disability rating, income and other factors (e.g., prisoner of war (POW) status), was determined using the VA Enrollment file (VIREC 2013). A Veteran's estimated income bracket was determined using census data detailing the median household income for the zip code associated with their residence (Thomas et al. 2006); this zip code was also used to determine the urbanicity of where the Veteran lived (Abrams et al. 2010). Overall health status was estimated through the CMS Hierarchical Condition Category risk-adjustment model for community-dwelling populations (Morgan et al. 2009; Pope et al. 2004).

**My HealthVet Registration and Use** Registration for My HealthVet and use of core portal features (medication refill, secure messaging, Blue Button, appointment view) was calculated for the Veterans in our sample within the year following their respective index date. Veterans were

**Table 2** Mental health diagnoses and corresponding ICD-9 Codes<sup>a</sup>

Depressive disorders	296.20–296.36, 296.50–296.55, 296.90, 300.4, 311
Post-traumatic stress disorder (PTSD)	309.81
Substance use disorders	291.x, 292.x, 303.xx, 304.xx, 305.xx [excluding 305.1, tobacco use disorder]
Anxiety disorders (not including PTSD)	300.0x, 300.2x, 300.3
Psychotic disorders (including schizophrenia)	295.x, 297.x, 298.x.
Adjustment disorders/stress reactions	308.x, 309.x [excluding 309.81, PTSD]
Bipolar disorders	296.00–296.16, 296.4x, 296.56, 296.6x, 296.8x
Military Sexual Trauma (MST)	MST Indicator (Recorded in VA Administrative Data)

<sup>a</sup>ICD-9 codes used to define each disorder (except for MST) were based on definitions detailed in Carlson et al. (2010)

considered to have used a portal feature if they had any use of that feature in this time-frame (as opposed to no use). Secure messaging use included read messages and/or sent messages. Blue Button use included any use of the feature.

## Statistical Analyses

To account for the random sample of non-users, all data for non-users was weighted and all statistics were calculated to reflect the weighting. Descriptive statistics were used to determine the proportion of Veterans with each mental health diagnosis (and multimorbidity of mental health diagnoses), and characterize the demographics of the sample along with the proportion of the sample who registered for My HealthVet and used each of the portal features. A series of logistic regression models were then conducted (separately for each mental health diagnosis). We used logistic regression models because the outcome variables of interest are discrete rather than continuous. In cases where there is a discrete outcome variable, modeling the outcome as a continuous variable in a linear regression model is problematic because the predicted outcomes from the model are not constrained to be between 0 and 1 (Greene 1992).

A set of unadjusted models determined the odds that a Veteran in our sample registered for a My HealthVet account. Among the Veterans who registered, we ran models estimating the odds of having used each of the portal features. The same process was then repeated to estimate adjusted models, which controlled for the potentially confounding influence of key demographic variables (e.g., gender, age, race, ethnicity, region of residence, VA enrollment group, income, urbanicity of residence, distance to VA, community score) and multimorbidity of mental health conditions on My HealthVet use. To test for multicollinearity, we also estimated the variance inflation factors for each variable; the results suggested that the variables in the regression were not highly correlated.

An alpha level of 0.05 was used to determine statistical significance. Statistical analyses were performed with STATA MP Version 14.2 software (StataCorp, College Station, TX). This study was approved by the Institutional Review Boards at the Edward Hines Jr. VA Hospital and Edith Nourse Rogers Memorial Veterans Hospital.

## Results

### Sample Description

The distribution of mental health conditions (including the proportion who had experienced MST) is presented in Table 3. Depressive disorders (52.8%) were the most prevalent diagnosis among our sample, while the experience

**Table 3** Distribution of mental health diagnoses among our sample (n = 159,581)

Diagnosis	Percentage of sample with diagnosis
Depressive disorders	52.77
Post-traumatic stress disorder (PTSD)	33.80
Substance use disorders	26.42
Anxiety disorders ( <i>not including PTSD</i> )	22.37
Psychotic disorders ( <i>including schizophrenia</i> )	11.00
Adjustment disorders/stress reactions	7.50
Bipolar disorders	5.42
Military sexual trauma (MST)	1.23
Multimorbidity ( <i>2 or more of the above diagnoses</i> )	42.26

of MST was the least prevalent (1.2%). Overall, our sample was comprised predominantly of males (93.3%) aged 60–69 years (37.8%), who were of white race/ethnicity (73.8%) and lived in urban settings (63.5%). Please see Table 4 for demographics broken down by each mental health condition. Of note, 13.7% of our sample as a whole were registered My HealthVet users.

### Descriptive Usage of My HealthVet Features by Mental Health Condition

The proportion of Veterans with each mental health diagnosis who used each My HealthVet feature is shown in Table 5. The proportion of Veterans who had registered for My HealthVet was highest among Veterans who had experienced MST (41.7%) and lowest among Veterans with a psychotic disorder (7.1%). The greatest proportion of Veterans within each diagnostic group used the medication refill function, followed by appointment view, secure messaging, and Blue Button.

### Odds of Usage of My HealthVet Features by Mental Health Condition

Results of the regression models are presented in Table 6 (unadjusted) and Table 7 (adjusted for potential confounding factors). Key findings of adjusted analyses are described below.

*Adjustment Disorder* Having an adjustment disorder was associated with increased odds of My HealthVet registration (OR 1.16; CI95 1.11–1.21), but decreased odds of use of the medication refill function (OR .86; CI95 .82–.90).

*Anxiety Disorder* Having an anxiety disorder was associated with increased odds of My HealthVet registration (OR 1.15; CI95 1.11–1.18), and increased odds of using the following portal features: medication refill (OR 1.05; CI95

**Table 4** Sample characteristics, by mental health diagnosis (n = 159,581)

	Age (% in each age category)							Gender (% male)	Race (% White)	Urban vs. rural (% rural)	% with multimorbidity <sup>a</sup>

<sup>a</sup>Defined as 2 or more of the conditions examined<sup>b</sup>Not including PTSD<sup>c</sup>Including schizophrenia

1.02–1.09); secure messaging (OR 1.05; CI95 1.02–1.09); Blue Button (OR 1.05; CI95 1.01–1.10).

**PTSD** Having PTSD was associated with increased odds of My HealtheVet registration (OR 1.25; CI95 1.22–1.29), and increased odds of using the following portal features: appointment view (OR 1.08; CI95 1.05–1.12); Blue Button (OR 1.14; CI95 1.09–1.19).

**Depressive Disorder** Having a depressive disorder was associated with increased odds of My HealtheVet registration (OR 1.23; CI95 1.20–1.27), and increased odds of using the following portal features: medication refill (OR 1.17; CI95 1.14–1.21); appointment view (OR 1.06; CI95 1.03–1.09); secure messaging (OR 1.05; CI95 1.02–1.09).

**Bipolar Disorder** Having bipolar disorder was associated with decreased odds of My HealtheVet registration (OR .79; CI95 .75–.83), and decreased odds of using the following portal features: medication refill (OR .87; CI95 .82–.92); appointment view (OR .91; CI95 .85–.97); Blue Button (OR .86; CI95 .79–.93).

**Psychotic Disorder** Having a psychotic disorder was associated with decreased odds of My HealtheVet registration (OR .47; CI95 .46–.49), and decreased odds of use of each portal feature: medication refill (OR .83; CI95 .78–.88); appointment view (OR .74; CI95 .70–.79); secure messaging (OR .82; CI95 .77–.88); Blue Button (OR .68; CI95 .62–.75).

**Substance Use Disorder** Having a substance use disorder was associated with decreased odds of My HealtheVet registration (OR .71; CI95 .69–.73), and decreased odds of use of each portal feature: medication refill (OR .76; CI95 .73–.78); appointment view (OR .88; CI95 .85–.91); secure messaging (OR .85; CI95 .81–.88); Blue Button (OR .94; CI95 .89–.98).

**MST** Having experienced MST was associated with increased odds of My HealtheVet registration (OR 2.52; CI95 2.27–2.80), and increased odds of use of each portal feature: medication refill (OR 1.23; CI95 1.15–1.32); appointment view (OR 1.42; CI95 1.32–1.52); secure messaging (OR 1.29; CI95 1.20–1.40); Blue Button (OR 1.39; CI95 1.27–1.53).

## Discussion

To the best of our knowledge, our study is among the first to examine use of the core features of a major integrated healthcare system's patient portal among individuals with various mental health diagnoses. Notably, we found that Veterans who had experienced MST were the most likely to use each of the VA's My HealtheVet portal features included in our analysis. This may be explained in part by the high rates of psychological and physiological comorbidities observed in Veterans who have experienced MST (Hyun et al. 2009;

<sup>d</sup>Values represent calculations for registered patients

Waitzkin et al. 2018; Yaeger et al. 2006), which may lead to greater healthcare use, in general, and unique care needs. Additionally, while both male and female Veterans experience it, MST is more prevalent among women Veterans; women Veterans tend to be younger than their male counterparts, and (while emerging evidence suggests this is mixed) may be more likely to be portal users in general (Goel et al. 2011; VA 2017; Wallace et al. 2016) and may also prefer to avoid VA hospitals if they are not comfortable there.

Veterans who had experienced MST were followed by those with stress and mood-related disorders (depression, anxiety disorders, and PTSD), while those with adjustment disorder, substance use disorder, bipolar disorder and psychotic disorder were the least likely to be registered My HealtheVet users and adopters of the main portal features. The differences we observed among groups align with previous studies indicating that My HealtheVet use tends to be

higher among Veterans with certain mental health diagnoses (e.g., anxiety, PTSD, depression) compared to others (e.g., substance use disorders, schizophrenia) (Shimada et al. 2014).

Proportionally, the most used features in our cohort were the medication refill and appointment view functions. These findings are consistent with previous research that has reported high use of the My HealtheVet medication refill feature among a national sample of VA patients (Shimada et al. 2014). However, our findings also extend those reported by Shimada et al. (2014), in that they suggest the appointment view function (which was not available at the time that study was conducted) is a highly utilized addition to the My HealtheVet platform. As of FY 2017, Veterans can also request appointments via a new online scheduling feature, which, in time, may become another widely used My HealtheVet feature. These results are promising

when considering the role that My HealthVet can have in mental healthcare provision, particularly that it may be a useful mechanism to facilitate access to care, appointment attendance, and medication adherence. Further, our findings suggest that My HealthVet features have the potential to improve healthcare processes and outcomes for Veterans with mental health diagnoses, and further highlight the importance of taking a comprehensive look at use of specific My HealthVet features in this vulnerable population.

### Medication Refill

When controlling for extraneous influences, we found that odds of use of this feature are increased and highest for Veterans who have experienced MST, and increased for those with depression and anxiety diagnoses; odds of use are decreased for those with adjustment disorder, bipolar, substance use, and psychotic disorders. This is consistent with research on adherence to psychotropic medications that indicates poor adherence among patients with psychotic disorders and bipolar disorder (Byerly et al. 2007; Sajatovic et al. 2007; Sajatovic et al. 2006; Velligan et al. 2009). It is also consistent with findings that substance use disorder is a predictor of medication non-adherence, for both psychotropic and non-psychotropic medication (Gonzalez et al. 2011; Swartz et al. 1998).

Overall, however, high rates of use for this feature indicate that it could be a useful clinical tool. Research suggests that clinicians often overestimate patients' medication adherence (Stephenson et al. 2012). By using the medication refill tool, patients offer members of their clinical team insight about the odds that they are medication adherent at any given point in time. More accurate understanding of medication adherence could pave the way for clinician-delivered (or portal-delivered) interventions to improve medication adherence or, when necessary, alter prescriptions to reduce barriers to adherence such as side effects.

### Secure Messaging

Secure messaging within the My HealthVet portal has been viewed positively by Veterans (Haun et al. 2014) and may improve health outcomes for patients with chronic conditions (Shimada et al. 2016). We found that, when controlling for extraneous influences, odds of secure messaging use are increased and highest for MST, followed by anxiety and mood-related disorders (depression), but are decreased for psychosis and substance use. The use of secure messaging systems within the field of psychiatry is rapidly increasing (Cronin et al. 2015). One randomized controlled trial found that patients were more likely to communicate psychosocial information by secure messaging than telephone (Lin et al. 2005). Additionally, clinicians report that secure

messaging decreases the threshold at which patients may initiate communication with their healthcare team, which is especially important between in-person clinical encounters (Nazi 2013).

Secure messaging may be a convenient and preferable mode of communication for patients as it allows them to send messages whenever they need to, affords them the ability to craft the content of their messages carefully in a pressure-free setting, and does not require that they repeat their personal information to staff responsible for phone triage (who may be unfamiliar to them) (Haun et al. 2013). Furthermore, some patients may find it easier to disclose personal information regarding their mental health through secure messaging as opposed to by telephone or in person, as this mode of communication may feel more discreet (Lin et al. 2005). Accordingly, it is important to leverage this feature to aid in mental health care for the diagnostic cohorts who are willing to use it, and to take steps to increase use among patients with mental health conditions who could greatly benefit from this feature but are less likely to take advantage of it. For instance, providers working with patients in the diagnostic categories less likely to use secure messaging may consider engaging in motivational interviewing or other kinds of communication with these patients to encourage engagement with this feature.

### Blue Button Download

By making information from their health record available for Veterans to view and print, use of the My HealthVet Blue Button feature may facilitate Veterans who also use non-VA services in sharing the information in their VA records with their non-VA providers (Turvey et al. 2014). Literature suggests that Veterans are highly satisfied with their ability to access their health information in My HealthVet (Nazi et al. 2013). Our data indicates that odds of Blue Button use are increased and highest for Veterans who have experienced MST, and increased for those with PTSD and anxiety, while odds of use are decreased for persons with bipolar disorder, substance use disorder, and psychotic disorders.

Proportionally, however, Blue Button was the least used feature among each of the mental health cohorts we looked at. This may be due in part to the fact that the data available via Blue Button was only significantly expanded in January 2013 (several months into our study time frame), including access to VA clinical progress notes which encompassed mental health notes. Additionally, since the completion of our study the more intuitive label of "health records" was added to the dashboard that appears on the My HealthVet home page to enhance Veteran navigation to the Blue Button, potentially increasing awareness and use of this portal feature. Our lack of insight into reasons for low uptake of

this feature among our cohort indicates that further evaluation of Veteran perspectives on this feature is warranted.

### Appointment View

We found that the odds of using the My HealtheVet appointment view feature are greater for Veterans with MST, PTSD and depression, and lower for those with bipolar, substance use, and psychotic disorders. A recent study by Kipping et al. (2016) found that patient portal use among individuals with “serious or persistent mental illness” resulted in decreased missed appointments and increased patient activation (Kipping et al. 2016). Taken together, these findings support the importance of future research to better understand and increase use of this feature in those with bipolar, substance use and psychotic disorders. This is especially true since mental health treatment engagement among Veterans tends to be low (Stecker et al. 2010) and appointment non-attendance has been associated with greater symptom severity, poorer social and vocational functioning, medication non-adherence, higher rates of suicide, dropout from services, and rehospitalization (Fischer et al. 2008; Killaspy et al. 2000; Mitchell and Selmes 2007).

Moreover, since the present study was completed, additional appointment management features have become available to Veterans through My HealtheVet, including the ability to receive email appointment reminders and request/schedule appointments. Accordingly, leveraging these various appointment management capabilities supported through MHV may increase the chances that Veterans remember upcoming appointments and attend them.

### Implications for Care

Tsai and Rosenheck (2012) reported that Veterans who use VA mental health services are equally likely to use My HealtheVet compared to their Veteran counterparts who receive VA care services unrelated to mental health. However, our data indicates that among Veterans with mental health concerns, some mental health conditions are associated with higher likelihood of My HealtheVet use than others. Specifically, individuals with bipolar disorder, psychotic disorders and substance use disorders have the lowest odds of registration and use of all My HealtheVet features. This is not surprising, given that management of these conditions comes with some unique challenges related to healthcare use and engagement in care (e.g., high comorbidity with homelessness, lower medication adherence, and cognitive impairment). While there may be additional barriers to My HealtheVet use among individuals with these conditions, our data identify where outreach efforts may be targeted to encourage these vulnerable cohorts to be more engaged in using My HealtheVet. Such efforts could also help guard

against the potential for disparities in use of My HealtheVet among Veterans with mental health diagnoses. In addition, while these efforts would be among many other non-portal-based strategies, introducing these patients to My HealtheVet could increase engagement with their mental and physiological health care in general, as well as other health-related technologies (e.g., clinical video telehealth, text messaging reminders) that the VA offers. It will be important for future research to explore the specific barriers to My HealtheVet use experienced within these populations, along with additional features these individuals would prefer My HealtheVet include (e.g., email reminders about medication refills), to improve engagement with the portal.

Findings that engagement with the portal was fairly high within some diagnostic groups (i.e., depression, anxiety, PTSD, and particularly, persons who have experienced MST) supports efforts to use My HealtheVet as an outreach platform for intervention/program delivery. For instance, an RCT being conducted by Simon et al. (2016) is using secure messaging to deliver a suicide prevention intervention to individuals determined to be at-risk for suicide attempt(s). Additionally, recent evidence suggests that use of online psychoeducation may reduce shame and increase self-directed empathy (Talbot et al. 2017), which may in turn reduce mental health associated stigma.

Given that stigma is commonly noted among the top barriers to mental healthcare engagement in the Veteran population (Hoge et al. 2004), using patient portals such as My HealtheVet to deliver mental health education and facilitate care has considerable potential to minimize related stigma and improve engagement with and adherence to mental health care. For instance, My HealtheVet features can be used to develop interventions or outreach efforts to promote psychological well-being and mental healthcare engagement. This may be particularly useful among Veterans who have experienced MST or have anxiety or mood-related diagnoses, as they are more likely to access resources and tools on this platform.

### Limitations

Our study used a MST indicator to identify a history of MST; however, past research has shown that this may underestimate the prevalence of MST in the Veteran population by 5% (Gundlapalli et al. 2017). Our analyses did not take into account overlap between mental health and other medical diagnoses, and as such, it may be that comorbid diagnoses are driving some of the associated portal use. Moreover, because the Veterans included in our sample were all new My HealtheVet users who first adopted use of the portal in FY13, the generalizability of our results to all Veteran users may be limited. Further, our analysis focused only on a core subset of portal features

and is only able to represent a point in time, while the patient portal itself, along with the features and content it offers, continues to evolve, a formidable challenge noted in previously published patient portal research agendas (Nazi et al. 2010). We conceptualized feature use as any use within a specified time period; future research could examine the frequency of use to account for one-time versus repeat users. Additionally, no indicator of illness severity was available in our dataset. Evaluating the relationship between illness severity and online portal use could provide important supplemental knowledge about how and when My HealthVet feature use is more or less likely to occur and how to leverage the platform for outreach and intervention delivery.

## Conclusions

Patient portals are a valuable tool for facilitating the patient-provider connection (e.g., via secure messaging) as well as facets of mental health treatment (e.g., via medication refills). Our data suggest that this tool is most likely to be used by individuals with depression, anxiety and stress-related disorders, as well as (and maybe particularly for) those who have experienced MST. However, based on our analysis, use of patient portals and their features is also limited among patients with other diagnoses (e.g., bipolar, substance use, and psychotic disorders). As My HealthVet may provide a less stigmatized access option for treatment facilitation/delivery, efforts are needed to understand why engagement has been low in these groups. Such insights may clarify how best to effectively increase portal engagement in these cohorts and/or provide insights into complementary or alternative channels (e.g., clinical video telehealth or texting reminders) more acceptable to them. Such efforts may reduce potential disparities that might arise from differences in portal use by persons with different mental health conditions.
